Polish Academy of Sciences
Warsaw, Poland

ABSTRACT. Semantic and logical problems arising in an incomplete information data base are investigated. A simple query language is described, and its semantics is defined, which refers the queries to the information about reality contained in a data base, rather than to reality itself. This approach, called the internal interpretation, is shown to lead in a natural way to the notions of a topological Boolean algebra and a modal logic related to S4, in the same way as referring queries directly to reality (external interpretation) leads to Boolean algebras and classical logic. An axiom system is given for equivalent (with respect to the internal interpretation) transformation of queries, which is then exploited as a basic tool in a method for computing the internal interpretation for a broad class of queries. An interesting special case of the problem of determining the internal interpretation amounts to deciding whether an assertion about reality (a "yes-no" query) is consistent with the incomplete information about reality contained in a data base. We give a solution to this problem, which relies on the classical combinatorial problem of distinct representatives of subsets.

KEY WORDS AND PHRASES: data base, incomplete information, query language semantics, implicit information, modal logic, relational model, null values.

Author’s address: Institute of Computer Science, Polish Academy of Sciences, P.O. Box 22, 00-901 Warsaw PKiN, Poland.

* This work was supported in part by the Polish Academy of Sciences under Contract MR I.3. It was also aided through visiting appointments by the Coordinated Science Laboratory, University of Illinois, and by the Laboratory for Computer Science, Massachusetts Institute of Technology.

Part of the results of this paper was presented at the Third International Conference on Very Large Data Bases, Tokyo, Japan, October 1977.
1. INTRODUCTION

For various reasons, the information contained in a real world data base is usually incomplete. This creates a need for developing methods to handle situations where a data base does not contain all information a user would like to know.

This paper follows a previous paper of the author [11], where a simple mathematical model of a data base with incomplete information was introduced. This model, called an information system (or just system), is based on attributes which can take values in specified attribute domains. Information incompleteness means that instead of having a single value of an attribute, we have a subset of the attribute domain, which represents our knowledge that the actual value is one of the values in this subset, though we do not know which one. This extends the idea of Codd’s null value [2], corresponding to the case where this subset is the whole attribute domain. A simple query language to communicate with an information system was also described in [11]. This language includes two kinds of queries, terms and formulas ("yes-no" queries). The expected response to a term is a list of objects with the property expressed by the term, while the response to a formula is a truth value, $T$ (truth) or $F$ (falsity). It was shown in [11] that when the information is incomplete the same query can be interpreted in many different ways, and to understand those differences two basic interpretations of a query were introduced, the external one and the internal one. The external interpretation refers the queries directly to the real world modeled in an incomplete way by the system, so that the external interpretation of a term $t$ is the set of objects which in reality have property $t$. Of course, the information contained in the system is, in
general, not sufficient to exactly determine this set. However, in [11] we give methods
to compute the best possible bounds on the external interpretation of \( t \) logically
derivable from the system, i.e.

(i) \( \| t \|_s \), the set of objects for which we can conclude, from the information
available in the system, that they are in the external interpretation of \( t \), and

(ii) \( \| t \|_e \), the set of objects for which we cannot rule out the possibility of
belonging to the external interpretation of \( t \).

In contrast to the external interpretation, the internal one refers the queries to the
system's information about the real world, rather than to the world itself, so that the
internal interpretation of a term \( t \) is the set of objects for which the information
contained in the system satisfies the conditions expressed by \( t \).

Although in the present paper we deal almost exclusively with internal interpretation
(so that the word "internal" will sometimes be omitted), the results obtained provide
solutions to some problems concerning the external interpretation which were left open
in [11]. The paper is organized as follows. In Section 2 we give basic definitions and we
survey those results of [11] which we shall need here. In Section 3 we precisely define
the internal interpretation of queries, and we investigate its basic properties. Then, in
Section 4, we give an axiom system for equivalent (with respect to the internal
interpretation) transformation of terms. The technique of equivalent transformation of
terms is then used as a basic tool in an algorithm for computing the internal
interpretation of an arbitrary term in an arbitrary system. We also prove that our
axiom system is complete in the usual logical sense, and we explain the relation of the
notion of a topological Boolean algebra to our semantics of terms. Then, in Section 5, we consider a sublanguage which seems to be interesting from the practical point of view. Determining the interpretation of a query in this sublanguage is much easier than in the general case. In particular, we are able to find the interpretation of any formula (which we were not able to do for the general language). Our method of computing the interpretation of an arbitrary formula in the sublanguage, which is described in Section 6, has a combinatorial flavor, and is related to the classical problem of distinct representatives of subsets [4]. In Section 7 we discuss some alternative approaches to defining the semantics of queries.
2. BASIC NOTIONS

In this section we give some basic definitions which we shall need in the rest of the paper. Some of them coincide with those in [11], where the reader is referred for more detail and motivation.

By an information system (or a system for short) we shall mean a triple

$$\mathcal{S} = \langle X, (D_i)_{i \in I}, U \rangle$$

where

(i) $X$ is a finite set of objects,
(ii) $I$ is a finite set of attributes,
(iii) $D$ is a nonempty set called the domain of attribute $i$,
(iv) $U$ is a function which associates with every attribute $i$ and every $a \in D_i$ a set $U(i,a) \subseteq X$, such that for every $i \in I$

$$\bigcup\{U(i,a): a \in D_i\} = X \quad (1)$$

Intentionally, $U(i,a)$ is the set of objects for which attribute $i$ possibly takes value $a$. According to this interpretation, we can determine, for every $x \in X$, and every $i \in I$, the set

$$\beta_i(x) = \{a \in D_i: x \in U(i,a)\} \quad (2)$$

of all possible values attribute $i$ can take for object $x$. Conversely, $U$ can be obtained from functions $\beta$, $i \in I$, by the formula

$$U(i,a) = \{x \in X: a \in \beta_i(x)\}. \quad (3)$$

We shall always assume that the set $X$ of objects, the set $I$ of attributes and the attribute domains $D_i$, $i \in I$ are fixed, and we shall often represent a system by functions
\( \beta_i, i \in I \) rather than by \( U \).

Notice that a system represented by \( \beta_i, i \in I \) may be treated as a relational model [1] with only one relation. However, in our case this relation consists of tuples \( \langle A_1, \ldots, A_n \rangle \) where each \( A_i \) is a subset of \( D_i \) rather than an element of \( D_i \) \( (A_i = \beta_i(x)) \).

For two systems \( \mathcal{R}_1 = \langle X, (D_i)_{i \in I}, U_1 \rangle \), and \( \mathcal{R}_2 = \langle X, (D_i)_{i \in I}, U_2 \rangle \), we say that \( \mathcal{R}_2 \) is an extension of \( \mathcal{R}_1 \) (in symbols \( \mathcal{R}_1 \leq \mathcal{R}_2 \), or \( \mathcal{R}_2 \geq \mathcal{R}_1 \)) if

\[
U_2(i, a) \subseteq U_1(i, a), \text{ for all } i \in I \text{ and } a \in D_i,
\]

or equivalently,

\[
\beta_i^2(x) \subseteq \beta_i^1(x), \text{ for all } i \in I \text{ and } x \in X,
\]

where \( \beta_i^1, i \in I \) and \( \beta_i^2, i \in I \) correspond to \( \mathcal{R}_1 \) and \( \mathcal{R}_2 \), respectively.

Intuitively, \( \mathcal{R}_1 \leq \mathcal{R}_2 \) means that the knowledge represented in \( \mathcal{R}_1 \) is contained in the knowledge represented in \( \mathcal{R}_2 \). Of course, \( \leq \) is a partial order. A system is called complete if \( U(i, a) \cap U(i, b) = \emptyset \) for all \( a, b \in D_i, a \neq b \); equivalently, if \( \beta_i(x) \) consists of a single value for all \( i \in I, x \in X \). For a theory of complete systems see [14]. A complete extension is called a completion.

Our query language consists of terms and formulas. Terms are built up from certain elementary parts called descriptors, and from constants \( 0, 1 \) by means of symbols for Boolean operations \( -, +, \cdot, \rightarrow \), and a special unary operation \( \neg \). Every descriptor is of the form \( \langle i, A \rangle \), where \( i \in I \) and \( A \subseteq D_i \). More exactly, \( A \) is in a fixed Boolean algebra \( B \) of subsets of \( D_i \). Descriptors will be informally written as \( \langle \text{LENGTH} \geq 50 \rangle \), \( \langle \text{SEX} = \text{M} \rangle \), \( \langle \text{SAL} < 10000 \rangle \), \( \langle \text{COLOR} = \text{RED} \rangle \) or simply \( \text{red} \), etc. An example of a term is

\[-(\langle \text{DEPT#} = 2 \rangle \cdot \langle \text{NAME} \neq \text{SMITH} \rangle + \langle \text{SAL} < 50000 \rangle \cdot \langle \text{AGE < 30} \rangle \).\]
The set of terms is denoted by $\mathcal{T}$.

Formulas are built up from atomic formulas $t = s$, where $t, s \in \mathcal{T}$, and from logical constants $T, F$ by means of logical connectives $\neg, \lor, \land, \Rightarrow$, and a special (modal) unary connective $\Box$. Finite disjunctions and conjunctions are abbreviated as $\bigvee_{j \in J} \phi_j$ and $\bigwedge_{j \in J} \phi_j$, respectively; $\neg(t = s)$ is denoted by $t \neq s$. An example of an (atomic) formula is $(\text{SEX} = F) \land (\text{SAL} > 10000)$ = 0. The set of all formulas is denoted by $\mathcal{F}$. Intuitively, both $\Box$ and $\square$ mean "in every possible extension of our present knowledge." A query (term or formula) is simple if it contains neither $\Box$ nor $\square$.

The interpretation of a query $Q$ in a complete system $\mathcal{S}$, called the value of $Q$ in $\mathcal{S}$ and denoted by $\|Q\|_{\mathcal{S}}$, or just $\|Q\|$, is defined in the natural way. We put

$$\|\langle i, A \rangle\| = \bigcup_{a \in A} U(i, a) = \{x \in X: \beta_f(x) \subseteq A\},$$

and we interpret $0, 1, \neg, +, \cdot, \rightarrow$ as $\varnothing, X$, and the set-theoretical operations of complementation, union, intersection and the operation "$(X \setminus A) \cup B''$, respectively; for formulas we define $\|t = s\| = T$ iff $\|t\| = \|s\|$, and we interpret the logical connectives in the natural way. Symbols $\Box$ and $\square$ are simply disregarded (there can be no proper extension of a complete system). Two queries $Q_1$ and $Q_2$ are externally equivalent (in symbols, $Q_1 \equiv Q_2$) if $\|Q_1\|_{\mathcal{S}} = \|Q_2\|_{\mathcal{S}}$ for every complete system $\mathcal{S}$ (here $D_i, i \in I$ are fixed but $X$ and $U$ are arbitrary). In [11], we gave an axiom system $B$ for externally equivalent transformation of queries, consisting of the following axiom groups:

B1. Substitutions of terms into the axioms of Boolean algebra, and the axioms of equality (see e.g. [15]).
B2. The following axioms concerning descriptors:

(i) \( \langle i, \mathcal{P} \rangle = 0 \), \( \langle i, D_i \rangle = 1 \),

(ii) \( \langle i, A \rangle + \langle i, B \rangle = \langle i, A \cup B \rangle \),

(iii) \( \langle i, A \rangle \cdot \langle i, B \rangle = \langle i, A \cap B \rangle \),

(iv) \( -\langle i, A \rangle = \langle i, D_i \setminus A \rangle \),

for all \( i \in I \), and all \( A, B \in \mathcal{R}_i \).

B3. Substitutions of formulas into the propositional calculus axioms.

B4. The axioms \( \Box t = t \) for every \( t \in \mathcal{T} \), and \( \Box \Phi = \Phi \) for every \( \Phi \in \mathcal{T} \).

(In fact B4 is missing in [11], where we consider only simple queries.) It can easily be proved that the axiom system B is complete, i.e. \( Q_1 \models Q_2 \) iff \( Q_1 \) can be transformed into \( Q_2 \) by using axioms in B. Our main task in this paper will be to generalize the definition of the value of a query to arbitrary (not necessarily simple) queries and to arbitrary (not necessarily complete) systems, and then to axiomatize this extended notion of value in the same way as the value of queries in complete systems is axiomatized by the axiom system B. We begin this program by giving, in the next section, a precise definition of the value \( \|Q\|_S \) of an arbitrary query \( Q \) in an arbitrary system \( S \).
3. INTERNAL INTERPRETATION OF QUERIES

Before introducing the formal definition of \( \|Q\|_\mathcal{L} \) for arbitrary \( Q \) and \( \mathcal{L} \), let us first give some intuitions connected with it. Our definition is based on a consistent approach where any query \( Q \) is interpreted as expressing an internal (with respect to the database) property of objects (if \( Q \) is a term) or a property of the data base as a whole (if \( Q \) is a formula); in other words, a term or formula expresses some conditions on the information available about an object or about the whole collection of objects, respectively. Any descriptor \( (i, A) \) will be understood as "known to have the value of attribute \( i \) in \( A \)," and the symbols \( \neg, +, \cdot \), will be interpreted as the usual set-theoretical operations of complementation, union and intersection, respectively, exactly in the same way as in the case of complete information. Notice that, in particular, the interpretation of red + blue is "known to be red or known to be blue" (rather than "known to be [red or blue]"); similarly, \( \neg red \) is interpreted as "not known to be red" (rather than "known not to be red").

The interpretation of \( \square t \) will be, roughly speaking, the set of all objects not only having (internal) property \( t \) now, but also in every — not necessarily complete — conceivable extension of our present knowledge. The interpretation of \( \Box \Phi \) is similar — it is \( T \) if and only if the assertion expressed by \( \Phi \), concerning the information on our collection of objects, is bound to remain true in every possible extension of our present knowledge. It should be emphasized that our interpretation of queries is intended for a user who is fully aware of the fact that the information available in the system may be incomplete, and who may explicitly refer to this incompleteness in his queries (by using
Definition 3.1. Let \( \mathcal{S} = \langle X_i, \mathcal{D}_i, \mathcal{U} \rangle \) be an arbitrary query. The value of \( \mathcal{Q} \) in \( \mathcal{S} \), denoted by \( \|\mathcal{Q}\|_{\mathcal{S}} \) (or \( \|\mathcal{Q}\| \) when \( \mathcal{S} \) is understood), is defined inductively as follows:

(i) \( \|\mathcal{i}, A\| = \{x \in X : \beta_i(x) \subseteq A\} \),
(ii) \( \|0\| = \emptyset \), \( \|1\| = X \),
(iii) \( \|-\| = X \setminus \|\| \),
(iv) \( \|\| + s\| = \|\| \cup \|s\| \),
(v) \( \|\| \cdot s\| = \|\| \cap \|s\| \),
(vi) \( \|\| \rightarrow s\| = (X \setminus \|\|) \cup \|s\| \),
(vii) \( \|\Box\|_{\mathcal{S}} = \{x \in X : \text{for every } \mathcal{S}' \supseteq \mathcal{S}, \ x \in \|\|_{\mathcal{S}'}\} \)

\[ = \bigcap_{\mathcal{S}'' \supseteq \mathcal{S}} \|\|_{\mathcal{S}''} \]

(viii) \( \|F\| = F \), \( \|T\| = T \),
(ix) \( \|\| = s\| = \begin{cases} T & \text{if } \|\| = \|s\| \\ F & \text{otherwise} \end{cases} \)

(x) \( \|\neg \Phi\| = \neg \|\Phi\| \),
(xi) \( \|\Phi \lor \Psi\| = \|\Phi\| \lor \|\Psi\| \),
(xii) \( \|\Phi \land \Psi\| = \|\Phi\| \land \|\Psi\| \),
(xiii) \( \|\Phi \rightarrow \Psi\| = \neg \|\Phi\| \lor \|\Psi\| \),
(xiv) \( \|\Box \Phi\|_{\mathcal{S}} = \begin{cases} T & \text{if } \|\Phi\|_{\mathcal{S}'} = T \text{ for every } \mathcal{S}' \supseteq \mathcal{S} \\ F & \text{otherwise} \end{cases} \)
\[
= \inf \{ \| \Phi \|_{\mathcal{S}} : \mathcal{S}' \succeq \mathcal{S} \}.
\]

(\inf \text{ refers to the natural ordering } F < T).

It will be convenient to denote \(-\Phi\) by \(\Diamond t\), for any term \(t\), and \(-\Box\Phi\) by \(\Diamond \Phi\), for any formula \(\Phi\). \(\Diamond t\) and \(\Diamond \Phi\) have a natural interpretation, given by the following theorem.

**THEOREM 3.1.** (a) For any term \(t\) and any system \(\mathcal{S}\)

\[
\| \Diamond t \|_{\mathcal{S}} = \{ x \in X : \text{ for some } \mathcal{S}' \succeq \mathcal{S}, x \in \| t \|_{\mathcal{S}} \}
\]

\[
= \bigcup_{\mathcal{S}' \succeq \mathcal{S}} \| t \|_{\mathcal{S}}
\]

(b) For any formula \(\Phi\) and any system \(\mathcal{S}\)

\[
\| \Diamond \Phi \|_{\mathcal{S}} = \left\{ \begin{array}{l}
T \text{ if for some } \mathcal{S}' \succeq \mathcal{S}, \| \Phi \|_{\mathcal{S}'} = T \\
F \text{ otherwise}
\end{array} \right.
\]

\[
= \sup \{ \| \Phi \|_{\mathcal{S}} : \mathcal{S}' \succeq \mathcal{S} \}.
\]

**Proof.**

(a) \(\| \Diamond t \|_{\mathcal{S}} = \| -\Box - t \|_{\mathcal{S}} = X \setminus \bigcap_{\mathcal{S}' \succeq \mathcal{S}} \| t \|_{\mathcal{S}'} = X \setminus \bigcap_{\mathcal{S}' \succeq \mathcal{S}} (X \setminus \| t \|_{\mathcal{S}'}) = X \setminus (X \setminus \bigcup_{\mathcal{S}' \succeq \mathcal{S}} \| t \|_{\mathcal{S}'}) = \bigcup_{\mathcal{S}' \succeq \mathcal{S}} \| t \|_{\mathcal{S}'}
\]

\[
= \{ x \in X : \text{ for some } \mathcal{S}' \succeq \mathcal{S}, x \in \| t \|_{\mathcal{S}'} \}.
\]

(b) \(\| \Diamond \Phi \|_{\mathcal{S}} = \| -\Box - \Phi \|_{\mathcal{S}} = -\| -\Box - \Phi \|_{\mathcal{S}}\)
\[ = \inf \{ \| \neg \diamond \| \rho : \mathcal{S}' \supseteq \mathcal{S} \} = \sup \{ \| \diamond \| \rho : \mathcal{S}' \supseteq \mathcal{S} \} \]

\[ = \sup \{ \| \Phi \| \rho : \mathcal{S}' \supseteq \mathcal{S} \} \]

\[
\begin{cases}
  T & \text{if for some } \mathcal{S}' \supseteq \mathcal{S}, \| \Phi \| \rho' = T \\
  F & \text{otherwise}
\end{cases}
\]

\[
\Box
\]

It should be emphasized that in Theorem 3.1 as well as in Definition 3.1 (vii) and (xiv) \( \mathcal{S}' \) is not assumed to be complete. If an operation \( \Box' \) were defined to be like \( \Box \), except that "for every \( \mathcal{S}' \supseteq \mathcal{S} \)" is replaced by "for every complete \( \mathcal{S}' \supseteq \mathcal{S} \)" then \( \Box' \) and \( \Box \) would not coincide. We have, for instance, \( \| \Box' (\langle \text{SEX} = M \rangle + \langle \text{SEX} = F \rangle) \| \rho = \mathcal{X} \), since in every completion \( \mathcal{S}' \) of \( \mathcal{S} \) \( \| \langle \text{SEX} = M \rangle + \langle \text{SEX} = F \rangle \| \rho' = 1 \| \rho' = \mathcal{X} \).

On the other hand, if the value of \( \text{SEX} \) for an object \( x \) is not known in \( \mathcal{S} \) then

\[ x \notin \| \langle \text{SEX} = M \rangle + \langle \text{SEX} = F \rangle \| \rho = \| \langle \text{SEX} = M \rangle \| \rho \cup \| \langle \text{SEX} = F \rangle \| \rho \],

and consequently \( x \notin \| \Box (\langle \text{SEX} = M \rangle + \langle \text{SEX} = F \rangle) \| \rho \) (notice that one of the extensions of \( \mathcal{S} \) is \( \mathcal{S} \) itself). We shall see in the next theorem that \( \Box' \) can be expressed by \( \Box \).

**THEOREM 3.2.** For any system \( \mathcal{S} \), any term \( t \), and any formula \( \Phi \)

(a) \[ \| \Box \langle t \rangle \| \rho = \{ x \in X : \text{for every completion } \mathcal{S}' \text{ of } \mathcal{S}, x \in \| t \| \rho' \} \]

(b) \[ \| \langle t \rangle \Box \| \rho = \{ x \in X : \text{for some completion } \mathcal{S}' \text{ of } \mathcal{S}, x \in \| t \| \rho' \} \]

(c) \[ \| \Box \Box \| \rho = \begin{cases} 
  T & \text{if for every completion } \mathcal{S}' \text{ of } \mathcal{S}, \| \Phi \| \rho' = T \\
  F & \text{otherwise}
\end{cases} \]

(d) \[ \| \Box \Box \| \rho = \begin{cases} 
  T & \text{if there is a completion } \mathcal{S}' \text{ of } \mathcal{S} \text{ with } \| \Phi \| \rho' = T \\
  F & \text{otherwise.}
\end{cases} \]
Proof. The theorem follows from the structure of the partial order \( \preceq \), more specifically, from the fact that for any \( \mathcal{S} \) there is a maximal element (i.e. a complete system) \( \mathcal{S}' \preceq \mathcal{S} \). Let \( \alpha(\mathcal{S}) \) be an arbitrary assertion with variable \( \mathcal{S} \) ranging over systems, which for any particular \( \mathcal{S} \) may be either true or false. Then

(i) \( (\forall \mathcal{S}' \preceq \mathcal{S}) \ (\exists \mathcal{S}'' \preceq \mathcal{S}') \ \alpha(\mathcal{S}'') \)

is equivalent to

(ii) for every complete \( \mathcal{S}' \preceq \mathcal{S} \), \( \alpha(\mathcal{S}') \).

Indeed, (i) implies

(\text{for every complete } \mathcal{S}' \preceq \mathcal{S}) \ (\exists \mathcal{S}'' \preceq \mathcal{S}') \ \alpha(\mathcal{S}''),

which is equivalent to (ii), since for complete \( \mathcal{S}' \) the only \( \mathcal{S}'' \preceq \mathcal{S}' \) is \( \mathcal{S}' \) itself.

Conversely, assume that (ii) holds. Then, by the structure of \( \preceq \), for every \( \mathcal{S}' \preceq \mathcal{S} \) there is at least one complete \( \mathcal{S}'' \preceq \mathcal{S}' \). But \( \mathcal{S}'' \preceq \mathcal{S} \), hence by (ii), \( \alpha(\mathcal{S}'') \) is true, which means that (i) holds. Taking \( \alpha(\mathcal{S}) \) to be \( x \in \| \mathcal{T} \| \), we obtain

\[ x \in \| \Box \phi \| \mathcal{S} \iff (\forall \mathcal{S}'' \preceq \mathcal{S}') \ x \in \| \phi \| \mathcal{S}' \]

\[ \iff (\forall \mathcal{S}' \preceq \mathcal{S}) \ (\exists \mathcal{S}'' \preceq \mathcal{S}') \ x \in \| \mathcal{T} \| \mathcal{S}'' \]

\[ \iff \text{for every complete } \mathcal{S}' \preceq \mathcal{S} \ x \in \| \mathcal{T} \| \mathcal{S}' \]

which proves (a). Similarly, taking \( \alpha(\mathcal{S}) \) to be \( \| \phi \| \mathcal{S} = T \) we have

\[ \| \Box \phi \| \mathcal{S} = T \iff (\forall \mathcal{S}' \preceq \mathcal{S}) \ (\exists \mathcal{S}'' \preceq \mathcal{S}') \ \| \phi \| \mathcal{S}'' = T \]

\[ \iff \text{for every complete } \mathcal{S}' \preceq \mathcal{S} \ \| \phi \| \mathcal{S}' = T, \]

which proves (c).

(b) We have

\[ \| \phi \| \mathcal{S} = \| \Box \phi \| \mathcal{S} = \| \Box \phi \| \mathcal{S} = \| \Box \phi \| \mathcal{S} = X \setminus \| \Box \phi \| \mathcal{S} \]
Hence, by (a),

\[ x \in \diamond \square \Phi \iff x \in \square \diamond \Phi \]

\[ \iff - (\text{for every complete } \mathcal{S}^* \supseteq \mathcal{S}, \ x \in \square \Phi^*) \]

\[ \iff \text{for some complete } \mathcal{S}^* \supseteq \mathcal{S}, \ x \in \diamond \Phi^*. \]

Similarly, \( \diamond \square \Phi = - \square \diamond \neg \Phi \), and we obtain (d) from (b). □

Two queries \( Q_1, Q_2 \) are said to be **internally equivalent** (in symbols, \( Q_1 \approx_i Q_2 \)) if \( \|Q_1\|_{\mathcal{S}} = \|Q_2\|_{\mathcal{S}} \) for every system \( \mathcal{S} \) (as in the definition of external equivalence, \( D_i, i \in I \) are fixed, but \( X \) and \( U \) are arbitrary). It follows trivially from the definition that the internal equivalence is stronger than external, i.e. \( Q_1 \approx_i Q_2 \) implies \( Q_1 \approx_e Q_2 \).

Of course the converse implication does not hold. For instance, \( \langle i, A \rangle + \langle i, B \rangle \approx_e \langle i, A \cup B \rangle \), but in general (if \( A \neq A \cup B = B \) \( \langle i, A \rangle + \langle i, B \rangle \not\approx_i \langle i, A \cup B \rangle \)). Indeed,

\[ \|\langle i, A \rangle + \langle i, B \rangle\| = \|\langle i, A \cup B \rangle\| = \{x \in X: \beta_i(x) \subseteq A \cup B\}, \]

and a subset of \( A \cup B \) need not be a subset of either \( A \) or \( B \). Another example is the equality \( -\langle i, A \rangle = \langle i, D_i \setminus A \rangle \) which is of course true under the external equivalence, and is not true (except for trivial cases) under the internal equivalence:

\[ \|\langle i, A \rangle\| = X \setminus \|\langle i, A \rangle\| = X \setminus \{x \in X: \beta_i(x) \subseteq A\} \]

\[ = \{x \in X: \beta_i(x) \cap (D_i \setminus A) \neq \emptyset\}, \]

while

\[ \|\langle i, D_i \setminus A \rangle\| = \{x \in X: \beta_i(x) \subseteq D_i \setminus A\}. \]

Putting these examples into more concrete terms, \( \langle \text{SEX} = M \rangle + \langle \text{SEX} = F \rangle \) is
interpreted as the set of persons whose sex is known, while \(\text{SEX}_{\{M,F\}}\) as the whole set \(X\) of persons; similarly, \(-\text{SEX} = M\) is interpreted as the set of persons who are not known to be men, while \(\text{SEX} \neq M\) as the set — in general smaller — of persons known not to be men (i.e., known to be women).
4. AXIOMS FOR INTERNAL INTERPRETATION OF TERMS

So far we know exactly what is the internal interpretation of a query (see Def. 3.1), but we do not know how to compute it. In this section we shall develop a method for evaluating the value of an arbitrary term in an arbitrary system (formulas will be treated in the next section where we give simple algorithms for determining the internal interpretation for queries of a special type).

Our method of computing $\|t\|$ will be based on transforming $t$ into some equivalent term for which determining $\|t\|$ is easy. The transformation process will be based on a set of axioms which completely axiomatize the internal equivalence, in the same sense as the axiom system $\mathbf{B}$ completely axiomatizes the external equivalence.

In order to develop our axiom system, we shall need some facts about topological Boolean algebras.

**Definition 4.1.** A topological Boolean algebra (TBA for short) is an algebra

$\langle B, +, \cdot, \rightarrow, \neg, 1, 0 \rangle$

such that $\langle B, +, \cdot, \rightarrow, \neg, 0, 1 \rangle$ is a Boolean algebra and $\lnot$ is a unary operation with the following properties

(i) \[ \lnot(a \cdot b) = \lnot a \cdot \lnot b \]

(ii) \[ \lnot a \leq a \]

(iii) \[ \lnot \lnot a = \lnot a \]

(iv) \[ \lnot 1 = 1 \]
for all \( a, b \in B \) (\( a \leq b \) abbreviates \( a \cdot b = a \)).

An example of a TBA is the Boolean algebra of subsets of a topological space with the operation of taking interior as \( \mathbb{I} \). A thorough study of TBAs, as well as the explanation of the elementary topological notions used here, can be found in Rasiowa and Sikorski [15]. The next lemma gives an example of a TBA which will play an important role in our considerations.

**Lemma 4.1.** Let \( (\mathcal{P}, \leq) \) be a partially ordered set. For all \( A, B \subseteq \mathcal{P} \) let

\[
\mathbb{I}A = \{ x \in \mathcal{P} : \text{ for every } y \geq x, \ y \in A \},
\]

\[
A \Rightarrow B = (\mathcal{P} \setminus A) \cup B,
\]

\[
-A = \mathcal{P} \setminus A.
\]

Then

\[
(\mathcal{P}(\mathcal{P}^c), \cup, \cap, =, \Rightarrow, \mathbb{I}, \varnothing, \mathcal{P}^c),
\]

(where \( \mathcal{P}(\mathcal{P}^c) \) denotes the set of all subsets of \( \mathcal{P}^c \)) is a TBA.

**Proof.** It is sufficient to show that the operation \( \mathbb{I} \) defined by (7) satisfies conditions (i) through (iv) of Definition 4.1.

(i) \[
\mathbb{I}(A \cap B) = \{ x \in \mathcal{P} : (\forall y \geq x) \ y \in A \cap B \}
\]

\[
= \{ x \in \mathcal{P} : (\forall y \geq x) \ y \geq A \cap \{ x \in \mathcal{P} : (\forall y \geq x) \ y \in B \}
\]

\[
= \mathbb{I}A \cap \mathbb{I}B.
\]

(ii) \[
\mathbb{I}A = \{ x \in \mathcal{P} : (\forall y \geq x) (\forall z \geq y) \ z \in A \}
\]

\[
= \{ x \in \mathcal{P} : (\forall z \geq x) \ z \in A \} = \mathbb{I}A.
\]
(ii) and (iv) are left to the reader. □

Notice that the example provided by this lemma is a special case of the before-mentioned general example based on a topological space. Indeed, (7) defines a topological interior operation, and hence endows \( \mathcal{X} \) with the structure of a topological space. It may be noted that the subsets

\[
\{ y \in \mathcal{X} : y \geq x \}, \ x \in \mathcal{X}
\]

form a basis of this topological space.

Similarly as \( \mathbf{I} \) behaves as a topological interior operation, the operation \( \mathbf{C} \), defined by

\[
\mathbf{C} a = -\mathbf{I} - a,
\]

can easily be shown to have the properties of a topological closure operation:

\[
\mathbf{C}(a + b) = \mathbf{C} a + \mathbf{C} b,
\]

\[
\mathbf{C} \mathbf{C} a = \mathbf{C} a,
\]

\[
a \leq \mathbf{C} a,
\]

\[
\mathbf{C} 0 = 0.
\]

The role of TBAs in the internal interpretation of terms is analogous to that of Boolean algebras in the external interpretation. The analogy is that we can perform internally equivalent transformations of terms using the axioms of TBA, more exactly, the axioms listed below.

**AXIOMS FOR TERMS UNDER INTERNAL INTERPRETATION.** The set \( \mathbf{T} \) of axioms consists of:

\[\text{TB1. Substitutions of terms into the axioms of TBA, i.e., axioms of Boolean algebra} \]
and

(i) \( \mathbb{D}(t,s) = \mathbb{D}t \mathbb{D}s \)

(ii) \( t \mathbb{D}t = \mathbb{D}t \)

(iii) \( \mathbb{D}t = \mathbb{D}t \)

(iv) \( \mathbb{D}1 = 1 \)

TB2. The following axioms concerning descriptors:

(v) \( \langle i, \emptyset \rangle = 0 \)

(vi) \( \langle i, D_p \rangle = 1 \)

(vii) \( \langle i, A \rangle \cdot \langle i, B \rangle = \langle i, A \cap B \rangle \)

for all \( i \in I, A, B \in \mathcal{P}_i \).

TB3. The axiom

(viii) \( \mathbb{D} \sum_{p=1}^{k} \left( -(i_p, A_p) + \sum_{q=1}^{n} (i_p, B^q_p) \right) \)

\[ = \sum_{p=1}^{k} \sum_{q=1}^{n} (i_p, (D_{i_p} \setminus A_p) \cup B^q_p) \]

for every positive integer \( k \), every sequence of positive integers \( n_1, \ldots, n_k \), every sequence of distinct attributes \( i_1, \ldots, i_k \) and \( A_1, B^1_1, \ldots, B^n_k \in \mathcal{R}_i \), \( 1 \leq p \leq k \).

The last axiom is fairly complicated but its role will hopefully become clear later, when we define the weak multiplicative normal form (see Def. 4.2).

Before proving that the axiom set TB properly axiomatize the internal interpretation of terms, we shall give an intuitive explanation why the notion of a TBA is relevant in
the context of internal interpretation, more exactly, why transforming terms according to the axioms of TBA preserves internal equivalence. To this end we consider the partially ordered set \((\mathcal{K}, \preceq)\), where \(\mathcal{K}\) is the set of all systems with fixed \(X\) and \((D_i)_{i \in I}\). This partially ordered set defines a TBA

\[
\mathcal{A} = (\mathcal{P}(\mathcal{K}), \cup, \cap, \Rightarrow, \neg, \emptyset, \mathcal{K}),
\]

(8)

see Lemma 4.1. For any \(x \in X\) and \(t \in \mathcal{T}\) let

\[
f_X(t) = \{\mathcal{L} \in \mathcal{K} : x \in \|t\|_\mathcal{L}\}.
\]

(9)

It will be proved (see the proof of Theorem 4.1) that \(f_X\) preserves all TBA operations, i.e. \(f_X(\square t) = \square f_X(t)\), \(f_X(t + s) = f_X(t) \cup f_X(s)\), etc. This means that, loosely speaking, the symbols \(\square\), \(+\), \(\cdot\) can be interpreted as operations in some TBA. Using this fact one can easily prove that if \(t = s\) can be derived from the axioms of TBA then \(f_X(t) = f_X(s)\) for every \(x \in X\), and consequently \(\|t\|_\mathcal{L} = \|s\|_\mathcal{L}\) for every \(\mathcal{L}\), i.e. \(t \equiv s\).

Let us formulate and prove it more precisely. We shall write \(t \equiv s\) if \(t\) can be transformed into \(s\) by using the axioms in TB. Obviously, \(\equiv\) is an equivalence relation on the set \(\mathcal{T}\).

**THEOREM 4.1** (Adequacy of the axiom system TB)

For any terms \(t, s\)

\[t \equiv s\] implies \(t \equiv s\).

*Proof.* It is sufficient to prove that if \(t = s\) is an axiom in TB then \(t \equiv s\). To this
end, let us consider the partially ordered set \( \langle \mathcal{X}, \leq \rangle \) of all systems with fixed \( X \) and 
\((D_i)_{i \in I}\) ordered by the relation of extension. The set \( \mathcal{P}(\mathcal{X}) \) of all subsets of \( \mathcal{X} \),
together with the usual set-theoretical operations and the operation \( \text{I} \) defined for every
\( A \subseteq \mathcal{X} \) by
\[
\text{I}A = \{ \mathcal{S} \in \mathcal{X} : \text{for every } \mathcal{S}' \supseteq \mathcal{S}, \mathcal{S}' \in A \},
\]
defines a TBA \( \mathcal{S} \), see (8). For any \( x \in X \), let the mapping
\[
f_x: \mathcal{T} \to \mathcal{P}(\mathcal{X})
\]
be defined by (9). The mapping \( f_x \) has the following properties:

\[
\begin{align*}
f_x(t + s) &= f_x(t) \cup f_x(s) \\
f_x(t - s) &= f_x(t) \cap f_x(s) \\
f_x(t \cdot s) &= f_x(t) \Rightarrow f_x(s) \\
f_x(-t) &= -f_x(t) \\
f_x(0) &= \emptyset \\
f_x(1) &= \mathcal{X} \\
f_x(\Box t) &= \text{I}f_x(t)
\end{align*}
\]

We shall prove the first and the last property. The other are left to the reader.

\[
\begin{align*}
f_x(t + s) &= \{ \mathcal{S} \in \mathcal{X} : x \in \| t + s \| \mathcal{S} \} \\
           &= \{ \mathcal{S} \in \mathcal{X} : x \in \| t \| \mathcal{S} \lor x \in \| s \| \mathcal{S} \} \\
           &= \{ \mathcal{S} \in \mathcal{X} : x \in \| t \| \mathcal{S} \} \cup \{ \mathcal{S} \in \mathcal{X} : x \in \| s \| \mathcal{S} \} \\
           &= f_x(t) \cup f_x(s).
\end{align*}
\]

\[
f_x(\Box t) = \{ \mathcal{S} \in \mathcal{X} : x \in \| \Box t \| \mathcal{S} \}
\]
Let \( t = s \) be an axiom of group TB2, i.e. a substitution of terms into an axiom of TBA. Since this axiom holds true in \( A \), we infer from the properties of \( f_x \) that \( f_x(t) = f_x(s) \) for every \( x \in X \). We illustrate this for axioms \( \cdot (s + r) = \cdot s + \cdot r \) and \( \Box(\cdot s) = \Box \cdot \Box s \):

\[
\begin{align*}
 f_x(\cdot (s + r)) & = f_x(t) \cap (f_x(s) \cup f_x(r)) \\
 & = (f_x(t) \cap f_x(s)) \cup (f_x(t) \cap f_x(r)) = f_x(\cdot s + \cdot r) \\
 f_x(\Box(\cdot s)) & = \Box(f_x(t) \cap f_x(s)) = \Box f_x(t) \cap \Box f_x(s) = f_x(\Box \cdot \Box s)
\end{align*}
\]

Now we shall prove the same for axioms of group TB2. As (v) and (vi) are trivial, we shall restrict ourselves to (vii):

\[
\begin{align*}
 f_x(\langle i, A \rangle \cdot \langle i, B \rangle) & = \{ \mathcal{S} \in \mathcal{H} : x \in \| \langle i, A \rangle \cdot \langle i, B \rangle \| \} \\
 & = \{ \mathcal{S} \in \mathcal{H} : x \in \| \langle i, A \rangle \| \cap \| \langle i, B \rangle \| \} \\
 & = \{ \mathcal{S} \in \mathcal{H} : \beta_f(x) \subseteq A \land \beta_f(x) \subseteq B \\
 & = \{ \mathcal{S} \in \mathcal{H} : \beta_f(x) \subseteq A \cap B \\
 & = \{ \mathcal{S} \in \mathcal{H} : x \in \| \langle i, A \cap B \rangle \| \} = f_x(\langle i, A \cap B \rangle).
\end{align*}
\]

(Here \( \beta_i, i \in I \) denote the functions uniquely corresponding to \( \mathcal{S} \)).

The last axiom to consider is (viii). This is the most difficult part of the theorem.

\[
f_x(\Box \sum_{p=1}^k \{ -\langle i_p, A_p \rangle + \sum_{q=1}^n \langle i_p, B_p \rangle \})
\]
\[ \{ \mathcal{S} \mid (\forall \mathcal{S}' \supseteq \mathcal{S}) \ x \in \bigcup_{p=1}^{k} \{ ||i_p A_p||_{\mathcal{S}'} \cup \bigcup_{q=1}^{n} \{ ||i_p B_p^q||_{\mathcal{S}'} \} \} \}
\]
\[ = \{ \mathcal{S} \mid (\forall \mathcal{S}' \supseteq \mathcal{S}) \ (\exists \ p) \ [ x \in ||i_p A_p||_{\mathcal{S}'} \lor (\exists \ q) x \in ||i_p B_p^q||_{\mathcal{S}'} ] \}. \]

Taking into account that

\[ x \notin ||i_p A_p||_{\mathcal{S}'} \iff \neg (A_p \subseteq \beta_i(x)) \]
\[ x \in ||i_p B_p^q||_{\mathcal{S}'} \iff \beta_i(x) \subseteq B_p^q \]

\((\beta_i, \ i \in I \text{ correspond to } \mathcal{S}'), \) and using (5), we obtain

\[ f_X(\bigoplus_{p=1}^{k} \[ -||i_p A_p|| + \sum_{p=1}^{n} \{ ||i_p B_p^q|| \} \]) \]
\[ \iff (\text{for all nonempty } Z_1 \subseteq \beta_i(x), \ldots, Z_k \subseteq \beta_i(x)) \]
\[ \ (\exists \ p) \ [ \neg (Z_p \subseteq A_p) \lor (\exists \ q) Z_p \subseteq B_p^q ] \]
\[ \iff (\exists \ p) \ (\text{for every nonempty } Z \subseteq \beta_i(x)) \ [ Z \subseteq A_p \Rightarrow (\exists \ q) Z \subseteq B_p^q ] \]
\[ \iff (\exists \ p) \ (\text{for every nonempty } Z \subseteq \beta_i(x) \cap A_p) \ (\exists \ q) Z \subseteq B_p^q \]
\[ \iff (\exists \ p) (\exists \ q) \beta_i(x) \cap A_p \subseteq B_p^q \]
\[ \iff (\exists \ p) (\exists \ q) \beta_i(x) \subseteq (D_i \setminus A_p) \cup B_p^q \]
\[ \iff x \in \bigcup_{p=1}^{k} \bigcup_{q=1}^{n} \{ ||i_p(D_i \setminus A_p) \cup B_p^q||_{\mathcal{S}} \} \]

\[ \mathcal{S} \in f_X(\sum_{p=1}^{k} \sum_{q=1}^{n} \{ ||i_p(D_i \setminus A) \cup B_p^q||_{\mathcal{S}} \}). \]

To sum up, we have proved that for every axiom \( t = s \) in TB and for every \( x \in X, \]
\( f_X(t) = f_X(s). \) But this means that for every such axiom, \( t \not\equiv s. \) Indeed,

\[ ||t||_{\mathcal{S}} = \{ x \in X : \mathcal{S} \in f_X(t) \} = \{ x \in X : \mathcal{S} \in f_X(s) \} = ||s||_{\mathcal{S}}. \]
Now the theorem follows from the fact that each time we use an axiom \( t = s \) in the transformation process, we replace an occurrence of \( t \) by \( s \) in some term \( r \). Since \( t \not\equiv i \), this operation does not change the value of \( r \). \( \Box \)

Putting our proof into more algebraic terms, we may illustrate it by the following commutative diagram:

\[
\begin{array}{ccc}
T & \rightarrow & \mathcal{P}(X) \\
\downarrow f & & \downarrow \phi \\
\prod_{x \in X} \mathcal{A}_x & \rightarrow & \\
\end{array}
\]

where \( \prod_{x \in X} \mathcal{A}_x \) denotes the direct product of TBAs \( \mathcal{A}_x \), each \( \mathcal{A}_x \) being a copy of \( \mathcal{A} = (\mathcal{P}(\mathcal{A}), \cup, \cap, \Rightarrow, \{ \}, \pi, \mathcal{E}) \), and where \( f = (f_x)_{x \in X} \), and

\[
\phi(a) = \{ x \in X : a \in \mathcal{A}_x \}
\]

for every \( a = (a_x)_{x \in X} \in \prod_{x \in X} \mathcal{A}_x \). The theorem follows from the fact that \( f \) is a homomorphism (i.e. it preserves all TBA operations) and that \( \prod_{x \in X} \mathcal{A}_x \) is a TBA.

We shall prove in this section that the converse of Theorem 4.1 holds as well, which means that the relations \( \not\equiv_i \) and \( \not\equiv_{TB} \) coincide (see Theorem 4.4).

Using Theorem 4.1 we can obtain some useful corollaries from the axioms in TB.

**Lemma 4.2.**

(a) \( \square\langle i, A \rangle \not\equiv_i \langle i, A \rangle \)

(b) \( \square\neg\langle i, A \rangle \not\equiv_i \langle i, D \setminus A \rangle \)
(c) \( \Box (i_1, A_1) + \ldots + (i_k, A_k) \approx \sum_i (i_1, A_1) + \ldots + (i_k, A_k) \)

for arbitrary (not necessarily distinct) \( i_1, \ldots, i_k \)

(d) \( \Box (-\langle i, A \rangle) + \ldots + (-\langle i, A \rangle) \approx \sum_i (i, D_i \setminus (A_1 \cap \ldots \cap A_k)) \)

(e) \( \Box (-\langle i_1, A_1 \rangle + \ldots + (-\langle i_k, A_k \rangle) \approx \sum_i (i_1, D_i_1 \setminus A_1) + \ldots + (i_k, D_i_k \setminus A_k) \)

whenever \( i_1, \ldots, i_k \) are pairwise distinct.

(f) \( \Diamond \langle i, A \rangle \approx \sum_i \langle i, D_i \setminus A \rangle \)

(g) \( \Diamond \langle i, A \rangle \approx \langle i, A \rangle \)

(h) \( \Diamond \langle i_1, A_1 \rangle + \ldots + (i_k, A_k) \approx \sum_i (-\langle i_1, D_i_1 \setminus A_1 \rangle + \ldots - \langle i_k, D_i_k \setminus A_k \rangle) \)

whenever \( i_1, \ldots, i_k \) are pairwise distinct.

(i) \( \Diamond \langle i_1, A_1 \rangle + \ldots + (i_k, A_k) \approx \sum_i (-\langle i, D_i \setminus (A_1 \cup \ldots \cup A_k) \rangle) \)

(j) \( \Diamond (-\langle i_1, A_1 \rangle + \ldots + (i_k, A_k) \approx \sum_i (-\langle i, A_1 \rangle + \ldots + (i_k, A_k) \)

for arbitrary (not necessarily distinct) \( i_1, \ldots, i_k \)

**Proof.** (a) through (e) correspond to some special cases of axiom (viii). For instance,

\[ \Box (-\langle i, A \rangle) \approx \sum_i (-\langle i, A \rangle + \langle i, A \rangle) \approx \langle i, D_i \setminus A \rangle. \]

(f) through (j) can be derived from (a) through (e). For instance,

\[ \Diamond \langle i_1, A_1 \rangle + \ldots + (i_k, A_k) \approx \sum_i (-\langle i_1, A_1 \rangle + \ldots (i_k, A_k) \)

\[ = -\Box (-\langle i_1, A_1 \rangle + \ldots + (i_k, A_k) \approx \sum_i (i_1, D_i_1 \setminus A_1) + \ldots + (i_k, D_i_k \setminus A_k) \)

\[ = -\langle i_1, D_i_1 \setminus A_1 \rangle + \ldots + (i_k, D_i_k \setminus A_k \rangle. \]

Now we are prepared to describe a method of determining the value of any term in
any system. The main tool in our approach is a certain normal form for terms.

**Definition 4.2.** (i) A term is *weakly coprimitive* if it is of the form

\[
\Sigma_{p=1}^k (- (i_pA_p) + \Sigma_{q=1}^m (i_pB_p^q))
\]

(10)

where the attributes \( i_1, \ldots, i_k \) are pairwise distinct.

(ii) A term is in *weak multiplicative normal form* (WMNF) if it is of the form

\[
\Pi_{k \in K} t_k
\]

where all \( t_k \)'s are weakly coprimitive.

Notice that any term in WMNF is simple. If we had axioms

\[
-(i,A) = (i,D_i \setminus A),
\]

\[
(i,A) + (i,B) = (i,A \cup B)
\]

then we would be able to transform (10) into

\[
\Sigma_{p=1}^k (i_p(D_i \setminus A_p) \cup \bigcup_{q=1}^m B_p^q)
\]

However, as we have already seen, these axioms are not valid under the internal interpretation.

**Lemma 4.3.** For any simple term \( t \) there is a term \( s \) in WMNF such that \( t \equiv_{TB}^\sim s \).

**Proof.** We shall describe an effective algorithm for transforming \( t \) into an internally equivalent term \( s \) in WMNF. By using the axioms of Boolean algebra we transform \( t \) into a product of sums, each sum consisting of some number of descriptors or negations
of descriptors. Each of these sums can be transformed into the form where descriptors are grouped according to attributes, say

$$\sum_{p=1}^{k} \left( \sum_{r \leq 1}^{m_p} -\langle i_p, A_p^r \rangle + \sum_{q \neq 1}^{n_p} \langle i_p, B_p^q \rangle \right)$$

(\(i_1, ..., i_k\) pairwise distinct). By De Morgan's Law and axiom (vii) of group TB2,

$$\sum_{r \leq 1}^{m_p} -\langle i_p, A_p^r \rangle \approx_{TB} -\prod_{r \leq 1}^{m_p} \langle i_p, A_p^r \rangle \approx_{TB} -\langle i_p, \bigcap_{r \leq 1}^{m_p} A_p^r \rangle.$$ 

This enables us to transform (11) into a weakly coprimitive term, and consequently to transform the whole term into WMNF. \(\Box\)

**Theorem 4.2.** For any term \(t\) there is a term \(s\) in WMNF such that \(t \approx_{TB} s\).

*Proof.* First we shall describe how to eliminate \(\Box\) from \(t\). If \(t\) contains an \(\Box\) then \(t\) must contain a subterm of the form \(\Box p\) with no \(\Box\) occurring in \(p\). By the previous lemma, \(p\) can be transformed into a term in WMNF, say \(p'\). But axiom (viii) enables us to directly transform \(\Box p'\) into a term in WMNF. In this way the number of occurrences of \(\Box\) is decreased by one. By repeating the above procedure we ultimately eliminate \(\Box\) from \(t\). Now it suffices to transform the resulting simple term into WMNF, which is possible by the previous lemma. \(\Box\)

Let us notice that the proof of Theorem 4.2 provides an effective algorithm for computing the value of any term in an arbitrary system. Indeed, in order to evaluate \(\|s\|\) for a term \(s\) not containing \(\Box\) we can directly apply Definition 3.1 ((i) through (vi)). For general terms, we may give the following convenient formulation of our method of
determining the internal interpretation.

THEOREM 4.3. For any term \( t \) and any system \( \mathcal{S} \) \( x \in \| t \|_\mathcal{S} \) if and only if after transforming \( t \) into WMNF, for every factor

\[
\sum_{p=1}^{k} (-\langle i_p, A_p \rangle + \sum_{q=1}^{\eta_p} \langle i_{p,q}, B_{p,q} \rangle)
\]

(12)

of this WMNF there is an attribute \( i_p \) such that

\[
\beta_{i_p}(x) \subseteq A_p \quad \text{or for some } q, \quad \beta_{i_p}(x) \subseteq B_{p,q}
\]

Proof. Follows directly from Definition 3.1 and from the fact that our process of transforming into WMNF preserves internal equivalence. \( \square \)

Example 4.1. Let \( t \) be the following term:

\[
-(\text{AGE} < 40) \cdot \Box (\text{SAL} > 10000) \cdot -(\text{SAL} > 20000) + (\text{SEX} = F) + (\text{SEX} = M)
\]

(13)

This query asks for objects with the value of AGE not known to be less than 40 (it may be known to be \( \geq 40 \)), which not only now but also in every possible extension of our present knowledge have the following (internal) property: either the value of SAL is known to be greater than 10000 and is not known to be greater than 20000 (it may be known to be \( \leq 20000 \)), or the value of SEX is known. We transform \( t \) into WMNF:

\[
\begin{align*}
t & \approx \neg \langle \text{AGE} < 40 \rangle \cdot \Box (\langle \text{SAL} > 10000 \rangle + \langle \text{SEX} = F \rangle + \langle \text{SEX} = M \rangle) \\
& \quad \cdot \neg (\langle \text{SAL} > 20000 \rangle + \langle \text{SEX} = F \rangle + \langle \text{SEX} = M \rangle) \\
& \approx \neg \langle \text{AGE} < 40 \rangle \cdot \Box (\langle \text{SAL} > 10000 \rangle + \langle \text{SEX} = F \rangle + \langle \text{SEX} = M \rangle) \\
& \quad \cdot \Box (\neg (\text{SAL} > 20000) + \langle \text{SEX} = F \rangle + \langle \text{SEX} = M \rangle)
\end{align*}
\]
\[ i \approx -\langle \text{AGE} < 40 \rangle \cdot \langle \text{SAL} > 10000 \rangle + \langle \text{SEX} = F \rangle + \langle \text{SEX} = M \rangle \]
\[ i \cdot \langle \text{SAL} \leq 20000 \rangle + \langle \text{SEX} = F \rangle + \langle \text{SEX} = M \rangle \]

(It is easy to see that in this particular case \( i \) can be further transformed into
\[ -\langle \text{AGE} < 40 \rangle \cdot \langle \text{SAL} \in (10000,20000) \rangle + \langle \text{SEX} = F \rangle + \langle \text{SEX} = M \rangle . \])

Now consider the following system:

<table>
<thead>
<tr>
<th>object</th>
<th>AGE</th>
<th>SAL</th>
<th>SEX</th>
</tr>
</thead>
<tbody>
<tr>
<td>( x_1 )</td>
<td>((0,\infty))</td>
<td>([0,\infty))</td>
<td>{M}</td>
</tr>
<tr>
<td>( x_2 )</td>
<td>{30}</td>
<td>{20000}</td>
<td>{F}</td>
</tr>
<tr>
<td>( x_3 )</td>
<td>((20,\infty))</td>
<td>((15000,30000))</td>
<td>{F,M}</td>
</tr>
<tr>
<td>( x_4 )</td>
<td>((35,45))</td>
<td>{15000}</td>
<td>{F,M}</td>
</tr>
</tbody>
</table>

By using Theorem 4.3, we obtain the value of (13):

\[ \|i\| = \{x_1,x_4\} . \]

It may be noted that in some cases it is useful to exploit the fact that

\[ -\langle i, A \rangle + \langle i, B \rangle \overset{TB}{\approx} \langle -\langle i, A \rangle + \langle i, B \rangle \cdot (-\langle i, A \rangle + \langle i, A \rangle) \rangle \]
\[ \overset{TB}{\approx} -\langle i, A \rangle + -\langle i, A \rangle \cdot \langle i, B \rangle + \langle i, A \rangle \cdot \langle i, B \rangle \overset{TB}{\approx} -\langle i, A \rangle + \langle i, A \cap B \rangle , \]

for transforming every factor (12) of a WMNF into

\[ \sum_{p=1}^{k} \left( -\langle i_p, A_p \rangle + \sum_{q=1}^{n_p} \langle i_p, A_p \cap B'_p \rangle \right) . \]
In this way we can eliminate from (12) the summands \((i_p, B_p^q)\) with \(A_p \cap B_p^q = \emptyset\).

By using the technique of transforming into WMNF we can prove the following theorem.

**THEOREM 4.4** (Completeness of the axiom system TB)

For any terms \(i, s\)

\[i \approx s \implies \text{TB} i \approx s.\]

**Proof.** Assume that \(i \not\approx s\), and transform \((-i + s)\cdot(-s + i)\) into a term \(r\) in WMNF,

\[\text{TB} r \approx (-i + s)\cdot(-s + i).\] We shall prove that \(r \not\approx \text{TB} 1\). Indeed, otherwise \(r\) would contain a factor \(r_p\) say

\[\sum_{p=1}^{k} \left( - (i_p, A_p) + \sum_{q=1}^{n_p} (i_p, B_p^q) \right)\]

with \(A_p \not\subseteq B_p^q\) for \(1 \leq p \leq k, 1 \leq q \leq n_p\) — notice that if \(A_p \subseteq B_p^q\) then, by (14),

\[-(i_p, A_p) + (i_p, B_p^q) \approx_{\text{TB}} -(i_p, A_p) + (i_p, A_p \cap B_p^q) \approx_{\text{TB}} -(i_p, A_p) + (i_p, A_p) \approx_{\text{TB}} 1.\]

Consider a system \(S\) with \(\beta_i(x) = D_i\) for all \(i \in I, x \in X\), and with a nonempty set \(X\) of objects. By axiom (viii) we get

\[\|\Box r_i\|_S = \| \sum_{p=1}^{k} \sum_{q=1}^{n_p} (i_p, (D_i \setminus A_p) \cup B_p^q) \|_S \]

\[= \bigcup_{p=1}^{k} \bigcup_{q=1}^{n_p} \| i_p, (D_i \setminus A_p) \cup B_p^q \|_S = \bigcup_{p=1}^{k} \bigcup_{q=1}^{n_p} \emptyset = \emptyset,\]

since \(A_p \not\subseteq B_p^q\) implies \((D_i \setminus A_p) \cup B_p^q \neq D_i\). Let us fix an object \(x \in X\). By the
definition of \( \|r\|_\mathcal{F} \) (see Def. 3.1 (vii)), there is a system \( \mathcal{F}' \supseteq \mathcal{F} \) such that \( x \notin \|r\|_\mathcal{F}' \), and consequently \( x \notin \|r\|_\mathcal{F''} \) (\( \|r\|_\mathcal{F''} \subseteq \|r\|_\mathcal{F'} \)). On the other hand, since \( t \equiv s \), we have \( \|r\|_\mathcal{F''} = \|s\|_\mathcal{F''} \) and

\[
\|r\|_\mathcal{F''} = \|(-t + s) \cdot (-s + t)\|_\mathcal{F''} \\
= ((X \setminus \|r\|_\mathcal{F'}) \cup \|s\|_\mathcal{F'}) \cap ((X \setminus \|s\|_\mathcal{F'}) \cup \|r\|_\mathcal{F'}) \\
= X \cap X = X,
\]

i.e., \( x \in \|r\|_\mathcal{F''} \). This contradiction shows that \( r \equiv^*_T 1 \) must hold. Hence we have

\[
\begin{align*}
& t \equiv^*_T t' \equiv^*_T t' \cdot (-t + s) \cdot (-s + t) \equiv^*_T t' \cdot (-t + s) \\
& \equiv^*_T t' \cdot (t + s) \cdot (-t + s) \equiv^*_T t' \cdot (s + (t \cdot -t)) \equiv^*_T t' \cdot s.
\end{align*}
\]

Similarly \( s \equiv^*_T t' \cdot s \), and consequently \( t \equiv^*_T s \). \( \Box \)

Combining this result with Theorem 4.1 we see that the relations \( \equiv^*_T \) and \( \equiv^*_T \) coincide.

In some cases it may be convenient to use another axiom system based on \( \# \) as a primitive operation (\( \# \) can be expressed as \(-\#-\)). The reader may easily verify that a (dual) complete axiom system \( \text{TB}^* \) can be obtained from \( \text{TB} \) by replacing axioms (i) through (iv) and (viii) by

(i)* \quad \#(t + s) = \#t + \#s

(ii)* \quad t \cdot \#t = t

(iii)* \quad \#t = \#t

(iv)* \quad \#0 = 0
(viii)* \[ \prod_{p=1}^{k} (\langle i_p, A_p \rangle \cdot \prod_{q=1}^{n} \langle i_p, B_p \rangle) \]

\[ = \prod_{p=1}^{k} \prod_{q=1}^{n} \langle i_p, (D_{i_p} \setminus A_p) \cup B_p \rangle \]

(with the same restrictions as in (viii)).

By using these axioms we can transform any term into \textit{weak additive normal form} (WANF), i.e. a sum of \textit{weakly primitive} terms of the form

\[ \prod_{p=1}^{k} (\langle i_p, A_p \rangle \cdot \prod_{q=1}^{n} \langle i_p, B_p \rangle) \]

\((i_1, \ldots, i_p\) pairwise distinct). Computing the internal interpretation is then carried out analogously as for WMNF.

Now we shall briefly discuss the internal interpretation of formulas. We shall not give any general method of computing \( \| \Phi \|_\rho \) — no such method is known to the author.

A reader who is familiar with the Kripke models for the modal logic S4 (see Kripke [8], Fitting [3, Chapter 3]) has undoubtedly noticed the similarity between Definition 3.1 and the definition of truth value of a formula in a Kripke model. An immediate corollary from this similarity is that transforming formulas according to the axioms of modal logic S4 preserves internal equivalence. For a discussion of S4 the reader is referred to [3,6,8,15]. Here we only note that TBAs play in S4 the same role as Boolean algebras in the classical logic, i.e., an expression is an S4-tautology if and only if its value is 1 in every TBA. An important difference between Definition 3.1 and a Kripke model is that the latter can be based on an arbitrary partial order, while our partial
order \( \preceq \) (the relation of extension) has some specific properties, e.g., for any \( \mathcal{S} \) there is a maximal element (complete system) \( \mathcal{S}' \succeq \mathcal{S} \). This causes that there are formulas which have value \( T \) in every system, yet which are not (substitutions of formulas into) \( \mathcal{S} \)-tautologies. Examples of such formulas are

\[
\Box \Diamond \Phi \Rightarrow \Diamond \Box \Phi \\
\Box \Diamond (\Phi \land \Psi) \Rightarrow \Box \Box \Phi \land \Diamond \Diamond \Psi \\
\Diamond \Box (\Phi \vee \Psi) \Rightarrow \Diamond \Diamond \Phi \vee \Diamond \Diamond \Psi
\]

(\( \Phi \equiv \Psi \) abbreviates \( (\Phi \Rightarrow \Psi) \land (\Psi \Rightarrow \Phi) \); see Theorem 3.2 for the intuition connected with these formulas). Other universally valid formulas are in our case

\[
\Box (t = 0) \iff \Diamond t = 0 \\
\Box (t \neq 0) \iff \Box t \neq 0 \\
\Diamond (t = 0) \iff \Box t = 0 \\
\Diamond (t \neq 0) \iff \Diamond t \neq 0
\]

It is not known to the author whether all these formulas completely axiomatize the internal equivalence of formulas (i.e. whether an analogon of Theorem 4.4 holds). While the problem of a complete axiomatization of internal equivalence — as well as that of evaluating \( \| \Phi \|_{\mathcal{S}} \) for any \( \Phi \) and \( \mathcal{S} \) — remain interesting logical open questions, it seems that the method of determining the internal interpretation for formulas of a special kind which we describe in the next section is quite sufficient for practical purposes.

Let us finally mention that our terms and formulas can be treated as respectively the open and closed formulas of a certain monadic modal Predicate Calculus (see Lipski [12]).
5. INTERNAL INTERPRETATION: A SIMPLIFIED LANGUAGE

The internal interpretation of queries described in the preceding section, although
precisely defined, may be not intuitively clear for a user, especially a casual one. The
main reason for that seems to be the fact that the meaning of the operation \( \square \) and the
connective \( \Box \) is less lucid than the meaning of the (formally more complicated)
operation \( \Box \land \Phi \) and connective \( \Box \lor \) (see Theorem 3.2). A user, who is in most cases
interested just in deducing as much information about reality as possible from
incomplete data, is likely to think of the system in terms of all completions of the
information available in the system, that is, all possibilities of how reality may turn out
to look like. On the other hand, in the definition of \( \| \Box r \| \) and \( \| \Box \Phi \| \) (see Def. 3.1 (vii)
and (xiv)) we take into consideration all extensions, not necessarily complete. Each such
extension may be thought of as an intermediate stage in a hypothetical process of
increasing the information contained in the system. What we do in the interpretation
described in the preceding section is — in a sense — indirectly defining (internal)
properties of objects (or of a system as a whole) by specifying properties of the possible
processes of increasing knowledge. It seems that such an expressive power may not be
necessary in a query language. With this in mind, we now propose a certain subclass of
queries as a basis for the query language.

Let us denote \( \Box \Phi t \) by surely \( t \), for any term \( t \). The set \( \mathcal{T}_0 \) of special terms is
defined to be the least set \( \mathcal{T}^\prime \) with the following two properties:

(i) 0, 1 and every descriptor is in \( \mathcal{T}^\prime \);

(ii) \(-t, surely t, (t + s), (t \ast s), (t \rightarrow s)\) are in \( \mathcal{T}^\prime \) whenever \( t, s \in \mathcal{T}^\prime \).
If we denote \(-\text{surely}\, t\) by possibly \(t\), then
\[\text{possibly } t \overset{i}{=} \neg \neg \neg \neg - t \overset{i}{=} \neg \neg \neg \neg \neg - t \overset{i}{=} \neg \neg t\]
and by Theorem 3.2, for any term \(t\) we have
\[\|\text{surely } t\|_\mathcal{F} = \bigcap \{\|\Phi\|_\mathcal{F} : \mathcal{F}' \text{ is a completion of } \mathcal{F}\}\]
(15)
\[\|\text{possibly } t\|_\mathcal{F} = \bigcup \{\|\Phi\|_\mathcal{F} : \mathcal{F}' \text{ is a completion of } \mathcal{F}\}\]
(16)

Similarly, by introducing the abbreviations \(\text{Surely } \Phi\) for \(\square \diamond \diamond \Phi\) and \(\text{Possibly } \Phi\) for
\(\neg \text{Surely } \neg \Phi\) we define the set \(\mathcal{T}_0\) of special formulas to be the least set \(\mathcal{T}'\) with the following two properties:

(i) \(T, F\) and every special atomic formula \(t = s\) \((t, s \in \mathcal{T}_0)\) are in \(\mathcal{T}'\).

(ii) \(\neg \Phi, \text{Surely } \Phi, (\Phi \lor \Psi), (\Phi \land \Psi), (\Phi \Rightarrow \Psi)\) are in \(\mathcal{T}'\) whenever \(\Phi, \Psi \in \mathcal{T}'\).

As before, Theorem 3.2 implies
\[\|\text{Surely } \Phi\|_\mathcal{F} = \inf \{\|\Phi\|_\mathcal{F} : \mathcal{F}' \text{ is a completion of } \mathcal{F}\}\]
(17)
\[\|\text{Possibly } \Phi\|_\mathcal{F} = \sup \{\|\Phi\|_\mathcal{F} : \mathcal{F}' \text{ is a completion of } \mathcal{F}\}\]
(18)

The following lemma gives some useful properties of surely.

**LEMMA 5.1**

(a) \(\text{surely } (i, A) \overset{i}{=} (i, A)\),

(b) \(\text{surely } - (i, A) \overset{i}{=} (i, D_i \setminus A)\),

(c) \(\text{surely } (t \cdot s) \overset{i}{=} \text{surely } t \cdot \text{surely } s\),

(d) \(\text{if } t \overset{e}{=} s \text{ then } \text{surely } t \overset{i}{=} \text{surely } s\).

**Proof.** (a) By Lemma 4.2 (b),
\[\text{surely } (i, A) \overset{i}{=} \square - \square - (i, A) \overset{i}{=} \square - (i, A)\]
\[
\text{i} \Rightarrow (\text{i} D_i \setminus (D_i \setminus A)) \Rightarrow (\text{i} D_i).
\]

(b) is proved similarly, by using Lemma 4.2 (a) and (b).

(c) By (15), in any system \( \mathcal{S} \) we have

\[
\| \text{surely} (t \cdot s) \| \mathcal{S} = \bigcap \{ \| s \| \mathcal{S} : \mathcal{S}' \text{ is a completion of } \mathcal{S} \}
\]

\[
= \bigcap \{ \| s \| \mathcal{S} : \mathcal{S}' \text{ is a completion of } \mathcal{S} \}
\]

\[
= \bigcap \{ \| t \| \mathcal{S} \cap \| s \| \mathcal{S} : \mathcal{S}' \text{ is a completion of } \mathcal{S} \}
\]

\[
= \| \text{surely} t \| \mathcal{S} \cap \| \text{surely} s \| \mathcal{S}
\]

(d) \( t \approx s \) means that \( \| t \| \mathcal{S} = \| s \| \mathcal{S} \) for any complete system \( \mathcal{S}' \). Hence, by (15),

\[
\| \text{surely} t \| \mathcal{S} = \bigcap \{ \| t \| \mathcal{S} : \mathcal{S}' \text{ is a completion of } \mathcal{S} \}
\]

\[
= \bigcap \{ \| s \| \mathcal{S} : \mathcal{S}' \text{ is a completion of } \mathcal{S} \}
\]

\[
= \| \text{surely} s \| \mathcal{S},
\]

that is, \( \text{surely} t \approx \text{surely} s. \quad \square \)

By virtue of Lemma 5.1 (d), if an occurrence of \( \text{surely} \) is within the scope of another one then the former can simply be deleted. Using this rule we can easily transform any special term to a Boolean combination of descriptors and terms of the
form surely \( s \), \( s \) not containing surely (moreover, any reasonable term entering a data base is, most probably, already of this form).

In order to efficiently eliminate surely from the resulting term we shall need another lemma. First, however, we give some auxiliary definitions.

A term is said to be in additive normal form (ANF) if it is a sum of primitive terms of the form \( \prod_{j \in J} \langle i_j A_j \rangle \), where \( i_p \neq i_q \) for \( p \neq q \), and \( \emptyset = A_j = D_i \) for all \( j \in J \).

Similarly, a term is in multiplicative normal form (MNF) if it is a product of coprimitive terms of the form \( \sum_{j \in J} \langle i_j A_j \rangle \), where, as before, all the attributes \( i_j \) are different and none of the descriptors reduces to 0 or 1. Of course, ANF and MNF are special cases of WANF and WMNF, respectively.

**Lemma 5.2.** If \( s \) is in MNF then surely \( s \equiv s \).

**Proof.** Let \( s \) be of the form \( \prod_i \sum_j \langle i_j A_j \rangle \). Then

\[
\begin{align*}
\text{surely } s & \equiv \prod_i \text{surely } \sum_j \langle i_j A_j \rangle \quad \text{(by Lemma 5.1(c))} \\
& \equiv \prod_i \emptyset - \sum_j \langle i_j A_j \rangle \quad \text{(by definition of surely)} \\
& \equiv \prod_i \emptyset - \prod_j \emptyset - \langle i_j A_j \rangle \quad \text{(by De Morgan's Law)} \\
& \equiv \prod_i \emptyset - \prod_j \emptyset - \langle i_j A_j \rangle \quad \text{(by Lemma 5.1(c))} \\
& \equiv \prod_i \emptyset - \prod_j \langle i_j, D_i \setminus A_j \rangle \quad \text{(by Lemma 4.2(b))} \\
& \equiv \prod_i \sum \langle i_j, D_i \setminus A_j \rangle \quad \text{(by De Morgan's Law)}
\end{align*}
\]
\[ \approx \prod_i \sum_j (i \cdot j \cdot A_j) \]  
(by Lemma 4.2(e))

\[ \approx_s \]  
\[ \square \]

Now we are ready to summarize the simplified method of computing the value of an arbitrary special term \( t \).

**Step 1.** Suppress nested occurrences of *surely* in \( t \).

**Step 2.** Replace every subterm *surely s* by a term in MNF externally equivalent to \( s \). (The process of transforming any simple term into MNF by using axioms in \( B \) is quite standard and the details are left to the reader, see also [11]).

**Step 3.** Transform the resulting term — which does not contain *surely* — into WMNF (see the proof of Lemma 4.3).

**Step 4.** Determine the value of the resulting WMNF term by using Theorem 4.3.

It is not difficult to give a complete set of axioms (involving — unlike TB — only special terms) for the internal interpretation of special terms.

**AXIOMS FOR SPECIAL TERMS UNDER INTERNAL INTERPRETATION.** The set \( S \) of axioms consists of:

1. Substitutions of special terms into the axioms of Boolean algebra and the axioms

   (i) \( \text{surely} (t \cdot s) = \text{surely} t \cdot \text{surely} s \)

   (ii) \( \text{surely surely } t = \text{surely } t \)

   (iii) \( \text{surely } 0 = 0 \)
(iv) surely $1 = 1$

S2. The following axioms concerning descriptors:

(v) $\langle i, B \rangle = 0$

(vi) $\langle i, D \rangle = 1$

(vii) $\langle i, A \cap B \rangle = \langle i, A \cap B \rangle$ for all $i \in I, A, B \in \mathcal{B}$.

S3. The axiom

(viii) surely $\sum_{p=1}^{k} (-\langle i_p, A_p \rangle + \sum_{q=1}^{n_p} \langle i_p, B_{p}^{q} \rangle)$

$$= \sum_{p=1}^{k} \langle i_p(D_{i_p} \setminus A_p) \cup \bigcup_{q=1}^{n_p} B_{p}^{q} \rangle$$

for every positive integer $k$, every sequence of positive integers $n_1, \ldots, n_k$, every sequence of distinct attributes $i_1, \ldots, i_k$ and all $A_p, B_1^p, \ldots, B_{n_p}^p \in \mathcal{B}_p$, $1 \leq p \leq k$.

The completeness of $S$ can be proved in the same way as the completeness of $TB$ — what is essential is that $S$ enables us to transform any special term into $WMNF$. We leave it to the reader.

As in the case of general terms, it may sometimes be convenient to use a dual axiom system, which is based on $possibly$ as a primitive operation. The reader may easily verify that such an axiom system $S^*$ can be obtained from $S$ by replacing axioms (i) through (iv) and (viii) by

(i)* $possibly (t + s) = possibly t + possibly s$

(ii)* $possibly possibly t = possibly t$
(iii)* possibly 0 = 0
(iv)* possibly 1 = 1
(viii)* possibly \( \prod_{p=1}^{k} (i_{p}, A_{p}) \cap \prod_{q=1}^{n} (i_{p}, B_{q}) \)

\[
= \prod_{p=1}^{k} (i_{p}(D_{p} \setminus A_{p}) \cup \bigcup_{q=1}^{n} B_{q}).
\]

The above axiom system is especially useful when we transform special terms into weak additive normal form.

**Example 5.1.** Let us consider the following special term \( t \):

\[
\text{possibly } ((\text{DEPT\#} = 4) \cdot (\text{NAME} = \text{BROWN})
\]

\[+ \text{ surely } ((\text{NAME} \neq \text{LIPSKI}) \cdot (\text{DEPT\#} = 1))\]

\[\cdot \text{ surely } ((\text{SAL} < 15000)\]

\[+ (\#\text{CHILDREN} > 3) \cdot (\text{SAL IN (10000,20000)}) \cdot (\text{STATUS} = \text{MARRIED})).\]

We show below the process of transforming \( t \) into WMNF. (We shall strictly follow the general method of transforming into WMNF described in this section, though in our particular example there are places where the transformation can be done more efficiently.)

\[
t \approx_{i} - \text{ surely } - (\text{DEPT\#} = 4) \cdot (\text{NAME} = \text{BROWN})
\]

\[+ (\text{NAME} \neq \text{LIPSKI}) \cdot (\text{DEPT\#} = 1)\]

\[\cdot \text{ surely } ((\text{SAL} < 15000) + (\#\text{CHILDREN} > 3))\]

\[\cdot (\text{SAL} < 15000) \cdot (\text{SAL IN (10000,20000)})\]
\[(\text{SAL} < 15000) + (\text{STATUS} = \text{MARRIED})\]

\[
\approx \sum_{i} \neg((\text{DEPT}\# \neq 4) + (\text{NAME} \neq \text{BROWN}))
\]

\[
\quad \cdot (\text{NAME} = \text{LIPSKI} + (\text{DEPT}\# \neq 1))
\]

\[
\quad \cdot (\text{SAL} < 15000) + (\#\text{CHILDREN} > 3) \cdot (\text{SAL} < 20000)
\]

\[
\quad \cdot (\text{SAL} < 15000) + (\text{STATUS} = \text{MARRIED})
\]

\[
\approx \sum_{i} \neg(\text{DEPT}\# \neq 4) \cdot \neg(\text{NAME} \neq \text{BROWN})
\]

\[
\quad + \neg(\text{NAME} = \text{LIPSKI}) \cdot \neg(\text{DEPT}\# \neq 1)
\]

\[
\quad \cdot (\text{SAL} < 15000) + (\#\text{CHILDREN} > 3) \cdot (\text{SAL} < 20000)
\]

\[
\quad \cdot (\text{SAL} < 15000) + (\text{STATUS} = \text{MARRIED})
\]

\[
\approx \sum_{i} \neg(\text{DEPT}\# \neq 4) + \neg(\text{NAME} = \text{LIPSKI}) \cdot \neg(\text{DEPT}\# \text{ IN } \{2,3,5\})
\]

\[
\quad -\neg(\text{NAME} = \text{LIPSKI}) \cdot (-\neg(\text{NAME} \neq \text{BROWN}) + \neg(\text{DEPT}\# \neq 1))
\]

\[
\quad \cdot (\text{SAL} < 15000) + (\#\text{CHILDREN} > 3) \cdot (\text{SAL} < 20000)
\]

\[
\quad \cdot (\text{SAL} < 15000) + (\text{STATUS} = \text{MARRIED})
\]

(In the transformation process we assumed that \(D_{\text{DEPT}\#} = \{1,2,3,4,5\}\)).
6. COMPUTING THE VALUE OF SPECIAL FORMULAS

In this section we shall develop a method to determine $\|\Phi\|$ for any special formula $\Phi$. It is interesting that this method has a combinatorial flavor and is quite different from that of computing the value of a special term. The main idea of our method can be explained on the following simple example.

Example 6.1. Suppose that three objects $x, y, z$ are classified with respect to color. Assume that the color of no object is known, and consider the following two situations:

<table>
<thead>
<tr>
<th>I</th>
<th>II</th>
</tr>
</thead>
<tbody>
<tr>
<td>possibly green objects</td>
<td>$A_1 = {x, y}$</td>
</tr>
<tr>
<td></td>
<td>$B_1 = {x, y}$</td>
</tr>
<tr>
<td>possibly red objects</td>
<td>$A_2 = {x}$</td>
</tr>
<tr>
<td></td>
<td>$B_2 = {x}$</td>
</tr>
<tr>
<td>possibly blue objects</td>
<td>$A_3 = {x, y}$</td>
</tr>
<tr>
<td></td>
<td>$B_3 = {x, z}$</td>
</tr>
</tbody>
</table>

(we do not exclude the possibility that an object is of another color than those listed above). We may ask the following question: "Is it possible that all colors, i.e. green, red and blue, are represented in our collection?" More formally, we ask for the value of the formula

$$\text{Possibly } ((\text{green} \neq 0) \land (\text{red} \neq 0) \land (\text{blue} \neq 0))$$

(19)

It is easy to see that the answer for our question is "no" in case I and "yes" in case II. Indeed, in case I we have only two objects $x, y$ to represent three colors, and in case II it may be that $x$ is red, $y$ is green and $z$ is blue. In order to put this observation into more general terms, we shall need the following definition. A sequence $r_1, \ldots, r_n$ is said
to be a **system of distinct representatives** (SDR) of a sequence of sets $S_1, ..., S_n$ if $r_i \in S_i$ for $1 \leq i \leq n$ and $r_i \neq r_j$ for $1 \leq i < j \leq n$. Coming back to our example we see that the relevant difference between case I and II is that there is no SDR for $A_1, A_2, A_3$, while there is one for $B_1, B_2, B_3$, namely $x, y, z$. This SDR provides an example of a possible completion of our information concerning the objects which makes formula (19) true.

We may say that in a general situation of this type, involving any number of of sets $S_1, ..., S_n$ corresponding to some mutually exclusive properties — call them "colors" — the element $r_i$ of an SDR of $S_1, ..., S_n$ plays the role of an object which "turns out to be of $i$th color."

The classical combinatorial theorem of Ph. Hall [4] asserts that an SDR for $S_1, ..., S_n$ exists if and only if

$$\left| \bigcup_{j \in J} S_j \right| \geq |J| \text{ for every } J \subseteq \{1, ..., n\}. $$

This condition is not very interesting from the algorithmic point of view, but efficient methods of testing for the existence of an SDR do exist. The best known algorithm was given by Hopcroft and Karp [5], in an equivalent formulation in terms of matchings in bipartite graphs. It may be useful to describe briefly this alternative formulation of the problem. Let $S_1, ..., S_n$ be subsets of $X = \{x_1, ..., x_m\}$. We construct a graph $G$ with vertices corresponding to $S_1, ..., S_n, x_1, ..., x_m$ with an edge $\{S_i, x_j\}$ joining $S_i$ and $x_j$ for all $S_i, x_j$ such that $x_j \in S_i$. By a **matching** we mean any set of edges with the property that no two edges in this set are incident to a common vertex. It is clear that $r_1, ..., r_n$ is an SDR of $S_1, ..., S_n$ if and only if $\{S_1, r_1\}, ..., \{S_n, r_n\}$ is a matching in $G$. 
(Remark: The algorithm of Hopcroft and Karp constructs an SDR, while we are merely interested in the existence; it would be interesting to know whether testing for the existence of an SDR is strictly easier than constructing one.)

Now we shall show how to decompose the problem of computing the value of an arbitrary special formula into some number of problems of the type described in Example 6.1. To this end we shall need some definitions and lemmas.

**Lemma 6.1.** For any formulas $\Phi, \Psi$

(a) $\text{Possibly } (\Phi \lor \Psi) \equiv \bigvee_i \text{Possibly } \Phi \lor \text{Possibly } \Psi,$

(b) if $\Phi \equiv \Psi$ then $\text{Possibly } \Phi \equiv \bigvee_i \text{Possibly } \Psi.$

**Proof.** Analogous to the proof of Lemma 5.1 (c), (d). $\square$

We may replace every occurrence of *Surely* by $\neg \text{Possibly } \neg$, and then, by Lemma 6.1 (b), suppress all those occurrences of *Possibly, surely, possibly* which are within the scope of *Possibly*. In this way we obtain a logical combination of special atomic formulas $t = s$ ($t, s \in T_0$), and formulas *Possibly* $\Phi$, where $\Phi$ is simple (i.e. it does not contain *Surely, Possibly, surely, or possibly*). The value of any special atomic formula can easily be computed by the methods developed in the previous section; it is convenient to make use of the fact

$$\|t = s\| = \begin{cases} T & \text{if } \|t \land \neg s + s \land \neg t\| = 0 \\ F & \text{otherwise} \end{cases}$$

Determining $\|\text{Possibly } \Psi\|$, $\Psi$ simple, is related to Example 6.1, and is much more difficult. We devote the rest of this section to showing how this can be done.
Definition 6.1. (i) A formula is elementary if it is of the form

\[ (t_0 = 0) \land \bigwedge_{k=1}^{n} (t_k \neq 0). \]  

where \( n \geq 0 \), \( t_0 \) is in MNF, \( t_1, \ldots, t_n \) are in ANF, and \( t_p \land t_q \vDash 0 \) for \( 0 \leq p < q \leq n \).

(ii) A formula is in special disjunctive normal form (SDNF) if it is of the form

\[ \bigwedge_{\psi \in \mathcal{L}} \psi \]

where all \( \psi \)'s are elementary.

We shall treat formulas (20) lacking the atomic formula \( t_0 = 0 \) also as elementary — to be more formal, we could add in such a case a dummy atomic formula \( 0 = 0 \).

We shall prove that every simple formula can be transformed into an externally equivalent formula in SDNF. Let us first notice that for any simple formula \( \Phi \) there exists a finite collection of terms \( s_1, \ldots, s_p \) (\( p \) depends on \( \Phi \)) such that \( s_i \land s_j \vDash 0 \) for \( 1 \leq i < j \leq p \), and every term occurring in \( \Phi \) is externally equivalent to a sum of some number of terms \( s_i \). We shall call such a collection a set of atoms with respect to \( \Phi \). One way to obtain \( s_1, \ldots, s_p \) is the following. Let \( J \) be the set of attributes represented in \( \Phi \). For any \( j \in J \), let

\[ \mathcal{A}_j(\Phi) = \{ A_j : (j, A) \text{ occurs in } \Phi \}, \]

\[ \mathcal{C}_j(\Phi) = \text{the set of all non-empty constituents of } \mathcal{A}_j(\Phi). \]

(Recall that a constituent of a family \( \{ A_1, \ldots, A_p \} \) of subsets of a set \( X \) is any set of the form \( A_1^{e_1} \cap \ldots \cap A_p^{e_p} \) where \( e_1, \ldots, e_p \in \{0,1\} \), and \( A_i^{e_i} \) denotes \( A_i \) if \( e_i = 1 \) and \( X \setminus A_i \) if \( e_i = 0 \), see Kuratowski and Mostowski [10], p. 21.) In other words, \( \mathcal{C}_j(\Phi) \) is the set of atoms of the Boolean algebra of subsets of \( D_j \) generated by \( \mathcal{A}_j(\Phi) \). Now let us define
\( \mathcal{A}(\Phi) = \{ \prod_{j \in J} A_j : \text{for every } j \in J, A_j \in C_j(\Phi) \} \).

It is easy to see that \( \mathcal{A}(\Phi) \) is a set of atoms with respect to \( \Phi \). Sometimes it is convenient to consider instead of \( C_j(\Phi) \) a partition of \( D_j \) which is finer than the partition into non-empty constituents of \( A_j(\Phi) \). For instance, for a real-valued attribute it may be useful to consider a partition into disjoint intervals, even if not all constituents are intervals. For simplicity, we shall denote such a finer partition by \( C_j(\Phi) \), too.

**Theorem 6.1.** For every simple formula \( \Phi \) there is a formula \( \Psi \) in SDNF such that \( \Phi \approx \Psi \).

**Proof.** We shall describe an effective procedure of transforming an arbitrary simple formula \( \Phi \) into SDNF.

**Step 1.** Replace every atomic formula \( t = s \) occurring in \( \Phi \) by the externally equivalent formula \( t \cdot s + s \cdot t = 0 \).

**Step 2.** By using the propositional calculus axioms transform the resulting formula into a disjunctive normal form \( \bigwedge_i \Phi_i \) where every \( \Phi_i \) is of the form

\[
\bigwedge_{k \in K^-} (u_k = 0) \land \bigwedge_{k \in K^+} (u_k \neq 0).
\] (23)

Now it is sufficient to show how to transform each such conjunction into SDNF.

**Step 3.** By using the equivalence
\[ \bigwedge_{k \in K^-} (u_k = 0) \approx \varepsilon (\sum_{k \in K^-} u_k) = 0, \]

replace the first part of (23) by the atomic formula \( t_0 = 0 \), where \( t_0 \) is the result of transforming \( \sum_{k \in K^-} u_k \) into MNF (for transforming into MNF see [11]).

**Step 4.** Replace the resulting formula, i.e.,

\[(t_0 = 0) \land \bigwedge_{k \in K^+} (u_k \neq 0), \quad (24)\]

by the (externally equivalent !) formula

\[(t_0 = 0) \land \bigwedge_{k \in K^+} (u_k - t_0 \neq 0) \]

and then by

\[(t_0 = 0) \land \bigwedge_{k \in K^+} (u_k \neq 0), \quad (25)\]

where \( u_k \) is the result of transforming \( u_k' - t_0 \) into ANF.

**Step 5.** Let \( \Theta \) be the second part of (25), i.e.,

\[ \bigwedge_{k \in K^-} (u_k \neq 0), \]

and let \( J \) be the set of attributes represented in \( \Theta \). For every \( j \in J \), determine \( \varepsilon_j(\Theta) \) (see (21), (22)). Since every \( u_k \) is in ANF, it is a sum of primitive terms of the form

\[ \prod_{j \in P} (v_{i,j}^-), \quad P \subseteq J. \]  

Transform each such primitive term into \( \prod_{j \in J} (v_{i,j}^-) \), by adding factors \( \langle j, D \rangle \approx 1 \) for every \( j \in J \setminus P \). Now replace every factor \( \langle j, D \rangle \) by the externally equivalent sum
\[ \sum (i, C) \]
\[ (C \subseteq A_j \land (C \in \Theta_j) : C \subseteq A_j) \]

(notice that \( A_j = \bigcup \{ C \in \Theta_j : C \subseteq A_j \} \) and that we have axiom (ii) of group B2), and then, by using the Distributive Law, transform the resulting product of sums into a sum of atoms with respect to \( \Theta \). By applying the above transformation to every primitive term in \( \nu_j \), and then suppressing repeated summands, we transform \( \nu_j \) into a sum of distinct atoms with respect to \( \Theta \), say \( \sum_{k \in M_j} s_k \).

**Step 6.** By using the equivalence

\[ (\sum_{k \in M_j} s_k) \neq 0 \Leftrightarrow \bigwedge_{k \in M_j} (s_k = 0), \]
transform (25) into

\[ (\lambda_0 = 0) \land \bigwedge_{j \in K^+} \bigwedge_{k \in M_j} (s_k = 0). \]

By applying the (logical) Distributive Law, and then suppressing repeated formulas \( s_k \neq 0 \) within every conjunction we ultimately arrive at a disjunction of elementary formulas, that is, SDNF. (It may then be useful to suppress repeated elementary formulas.) \( \square \)

**Example 6.2.** Let \( \Phi \) be the formula

\[
(\langle \text{SEX} = F \rangle \neq \langle \text{AGE} \geq 25 \rangle)
\]
\[ \land [(\langle \text{AGE} < 30 \rangle \cdot \langle \text{SAL} > 30000 \rangle = 0) \land (\langle \text{SEX} = M \rangle = 0) \]
\[ \lor (\langle \text{AGE} \geq 25 \rangle \cdot \langle \text{SAL} < 15000 \rangle \cdot \langle \text{SEX} = F \rangle \neq 0) \]
\[ \land (\langle \text{SEX} = M \rangle \cdot \langle \text{SAL} \geq 15000 \rangle \neq 0)] \quad (26)
\]
Below we show some of the stages of transforming $\Phi$ into SDNF:

$$
\Phi \approx_{e} (\langle \text{SEX} = F \rangle \cdot \langle \text{AGE} < 25 \rangle + \langle \text{SEX} = M \rangle \cdot \langle \text{AGE} \geq 25 \rangle \neq 0) \\
\wedge (\langle \text{AGE} < 30 \rangle \cdot (\text{SAL} > 30000) = 0) \wedge (\langle \text{SEX} = M \rangle = 0) \\
\vee (\langle \text{SEX} = F \rangle \cdot (\langle \text{AGE} < 25 \rangle + \langle \text{SEX} = M \rangle \cdot (\langle \text{AGE} \geq 25 \rangle \neq 0) \\
\wedge ((\langle \text{AGE} \geq 25 \rangle \cdot (\text{SAL} < 15000) \cdot (\langle \text{SEX} = F \rangle \neq 0) \\
\wedge (\langle \text{SEX} = M \rangle \cdot (\text{SAL} \geq 15000) \neq 0)
$$

$$
\approx_{e} ((\langle \text{AGE} < 30 \rangle + (\langle \text{SEX} = M \rangle) \cdot ((\text{SAL} > 30000) + (\langle \text{SEX} = M \rangle) = 0) \\
\wedge ((\langle \text{SEX} = F \rangle \cdot (\langle \text{AGE} < 25 \rangle \cdot (\langle \text{AGE} \geq 30 \rangle \cdot (\langle \text{SEX} = F \rangle) + (\langle \text{SEX} = F \rangle \cdot (\langle \text{AGE} < 25 \rangle \cdot (\text{SAL} \leq 30000) \cdot (\langle \text{SEX} = F \rangle) + (\langle \text{SEX} = M \rangle \cdot (\langle \text{AGE} \geq 25 \rangle \cdot (\langle \text{AGE} \geq 30 \rangle \cdot (\langle \text{SEX} = F \rangle) + (\langle \text{SEX} = M \rangle \cdot (\langle \text{AGE} \geq 25 \rangle \cdot (\text{SAL} \leq 30000) \cdot (\langle \text{SEX} = F \rangle) \neq 0) \\
\vee (\langle \text{SEX} = F \rangle \cdot (\langle \text{AGE} < 25 \rangle \neq 0) \\
\wedge (\langle \text{AGE} \geq 25 \rangle \cdot (\text{SAL} < 15000) \cdot (\langle \text{SEX} = F \rangle \neq 0) \\
\wedge (\langle \text{SEX} = M \rangle \cdot (\text{SAL} \geq 15000) \neq 0) \\
\vee (\langle \text{SEX} = M \rangle \cdot (\langle \text{AGE} \geq 25 \rangle \neq 0) \\
\wedge (\langle \text{AGE} \geq 25 \rangle \cdot (\text{SAL} < 15000) \cdot (\langle \text{SEX} = F \rangle \neq 0) \\
\wedge (\langle \text{SEX} = M \rangle \cdot (\text{SAL} \geq 15000) \neq 0)
$$

The first two parts of the above disjunction are already elementary formulas (strictly speaking, the first one becomes an elementary formula after some simple reductions). Let $\Theta$ be the third part. We have

$$
\delta_{\text{AGE}}(\Theta) = \{(0, 25), [25, \infty)\}.
$$
\[ \Theta \models (\text{SEX} = M) \land (\text{AGE} \geq 25) \land (\text{SAL} < 15000) \land (\text{SAL} \geq 15000) \neq 0 \]
\[ \land (\text{AGE} \geq 25) \land (\text{SAL} < 15000) \land (\text{SEX} = F) \neq 0 \]
\[ \land (\text{SEX} = M) \land (\text{SAL} \geq 15000) \land (\text{AGE} < 25) \land (\text{AGE} \geq 25) \neq 0 \]

After applying Distributive Law and performing some simple reductions, we finally obtain the SDNF of \( \Phi \):

\[ (\text{AGE} < 30) \land (\text{SEX} = M) \land (\text{SAL} > 30000) \land (\text{SEX} = M) = 0 \]
\[ \land (\text{SEX} = F) \land (\text{AGE} < 25) \land (\text{SAL} \leq 30000) \neq 0 \]
\[ \lor (\text{SEX} = F) \land (\text{AGE} < 25) \neq 0 \]
\[ \land (\text{AGE} \geq 25) \land (\text{SAL} < 15000) \land (\text{SEX} = F) \neq 0 \]
\[ \land (\text{SEX} = M) \land (\text{SAL} \geq 15000) \neq 0 \]
\[ \lor (\text{SEX} = M) \land (\text{AGE} \geq 25) \land (\text{SAL} < 15000) \neq 0 \]
\[ \land (\text{AGE} \geq 25) \land (\text{SAL} < 15000) \land (\text{SEX} = F) \neq 0 \]
\[ \land (\text{SEX} = M) \land (\text{SAL} \geq 15000) \land (\text{AGE} < 25) \neq 0 \]
\[ \lor (\text{SEX} = M) \land (\text{AGE} \geq 25) \land (\text{SAL} < 15000) \neq 0 \]
\[ \land (\text{AGE} \geq 25) \land (\text{SAL} < 15000) \land (\text{SEX} = F) \neq 0 \]
\[ \land (\text{SEX} = M) \land (\text{SAL} \geq 15000) \land (\text{AGE} \geq 25) \neq 0 \]
\[ \lor (\text{SEX} = M) \land (\text{AGE} \geq 25) \land (\text{SAL} \geq 15000) \neq 0 \]
\[ \land (\text{AGE} \geq 25) \land (\text{SAL} < 15000) \land (\text{SEX} = F) \neq 0 \]
\[ \land (\text{SEX} = M) \land (\text{SAL} \geq 15000) \land (\text{AGE} < 25) \neq 0 \]

\[ \lor (\text{SEX} = M) \land (\text{AGE} \geq 25) \land (\text{SAL} \geq 15000) \neq 0 \]

\[ \land (\text{AGE} \geq 25) \land (\text{SAL} < 15000) \land (\text{SEX} = F) \neq 0 \]  \hspace{1cm} (27)

Notice that in order to be more efficient we did not exactly follow the general pattern of transformation described in the proof of Theorem 6.1.

All we need now is a method for computing the value of Possibly \( \Phi \), \( \Phi \) elementary. Indeed, let us transform a simple formula \( \Psi \) into an externally equivalent formula in SDNF, say \( \bigwedge_{i \in L} \Psi_i \), where the \( \Psi_i \) are elementary. By Lemma 6.1,

\[ \text{Possibly } \Psi \equiv \bigvee_i \text{Possibly } \bigwedge_{i \in L} \Psi_i \equiv \bigwedge_{i \in L} \Psi_i. \]

The last step is provided by the next theorem.

THEOREM 6.2. Let \( \Phi \) be an elementary formula of the form

\[ (t_0 = 0) \land \bigwedge_{k=1}^{n} (t_k \neq 0) \]  \hspace{1cm} (28)

Then \( \|\text{Possibly } \Phi\|_{\mathcal{F}} = T \) if and only if the following two conditiona are satisfied:

(i) \( \|\text{surely } t_0\|_{\mathcal{F}} = \varnothing \),

(ii) the sequence \( \|\text{possibly } t_1\|_{\mathcal{F}}, \ldots, \|\text{possibly } t_n\|_{\mathcal{F}} \) has an SDR.

Proof. If \( \|\text{Possibly } \Phi\|_{\mathcal{F}} = T \) then, by (18), there is a completion \( \mathcal{F}' \succeq \mathcal{F} \) such that \( \|\Phi\|_{\mathcal{F}'} = T \), i.e. \( \|t_0\|_{\mathcal{F}'} = \varnothing \) and \( \|t_k\|_{\mathcal{F}'} \neq \varnothing \), \( 1 \leq k \leq n \). By (15), it follows that \( \|\text{surely } t_0\|_{\mathcal{F}} = \varnothing \), and since \( t_{p+1}^{p+1} \varnothing \approx 0 \) for \( 1 \leq p < q \leq n \), the sets \( \|t_1\|_{\mathcal{F}'}, \ldots, \|t_n\|_{\mathcal{F}'} \) are mutually disjoint, so that we may choose distinct elements \( x_1 \in \|t_1\|_{\mathcal{F}'}, \ldots, x_n \in \|t_n\|_{\mathcal{F}'} \). But (16) implies \( \|t_k\|_{\mathcal{F}} \leq \|\text{possibly } t_k\|_{\mathcal{F}} \), hence \( x_1, \ldots, x_n \) is an SDR of the sequence \( \|\text{possibly } t_1\|_{\mathcal{F}}, \ldots, \|\text{possibly } t_n\|_{\mathcal{F}} \).
Conversely, suppose that \( \|\text{surely } t_0\|_{\mathcal{F}} = \varnothing \) and that \( x_1, \ldots, x_n \) is an SDR of the sequence \( \|\text{possibly } t_1\|_{\mathcal{F}}, \ldots, \|\text{possibly } t_n\|_{\mathcal{F}} \). Then, by (15) and (16), there exist completions \( \mathcal{F}_0, \mathcal{F}_1, \ldots, \mathcal{F}_n \) such that \( \|t_0\|_{\mathcal{F}_0} = 0 \), \( x_k \in \|t_k\|_{\mathcal{F}_k} \) for \( 1 \leq k \leq n \). Let \( (\beta_i^k)_{i \in k}, 0 \leq k \leq n \) correspond to \( \mathcal{F}_k \) for \( 0 \leq k \leq n \), respectively. We define a completion \( \mathcal{F}'' \) by

\[
\beta_i^k(x) = \begin{cases} 
\beta_i^k(x) & \text{if } x = x_k \text{ for some } k, \ 1 \leq k \leq n \\
\beta_i^0(x) & \text{otherwise}
\end{cases}
\]

It is easy to see that \( x_k \in \|t_k\|_{\mathcal{F}'}, 1 \leq k \leq n \), and \( \|t_0\|_{\mathcal{F}}', = \varnothing \) (since \( x_k \in \|t_k\|_{\mathcal{F}} \) and \( t_0 \not\preceq t_k \)). Consequently, \( \|\Phi\|_{\mathcal{F}} = T \), i.e., \( \|\text{Possibly } \Phi\|_{\mathcal{F}} = T \). □

Notice that in the proof we did not make use of the fact that \( t_0 \) was in MNF and that the \( t_k, 1 \leq k \leq n \) were in ANF. In fact, these assumptions in the definition of an elementary formula (see Def. 6.1(i)) were made only to make computing the value easier — if \( t_0 \) is in MNF then, by Lemma 5.2,

\[
\|\text{surely } t_0\| = \|t_0\|; \tag{29}
\]

similarly, if \( t_k \) is in ANF, say \( \sum_p \prod_q \langle i_{pq}, A_{pq} \rangle \), then

\[
\|\text{possibly } t_k\| = \|\text{surely } \prod_p \sum_q \langle i_{pq}, D_{ipq} \setminus A_{pq} \rangle \|
\]

\[
= \|\prod_p \sum_q \langle i_{pq}, D_{ipq} \setminus A_{pq} \rangle \|
\]

\[
= \| \sum_p \prod_q -\langle i_{pq}, D_{ipq} \setminus A_{pq} \rangle \|.
\tag{30}
\]

Example 6.3. Consider a very simple system represented by the following table:
<table>
<thead>
<tr>
<th>object</th>
<th>AGE</th>
<th>SAL</th>
<th>SEX</th>
</tr>
</thead>
<tbody>
<tr>
<td>$x_1$</td>
<td>(20,40)</td>
<td>(0,∞)</td>
<td>{M}</td>
</tr>
<tr>
<td>$x_2$</td>
<td>{35}</td>
<td>(30000,40000)</td>
<td>{F,M}</td>
</tr>
<tr>
<td>$x_3$</td>
<td>(30,40)</td>
<td>(20000,30000)</td>
<td>{F}</td>
</tr>
<tr>
<td>$x_4$</td>
<td>[20,30)</td>
<td>(10000,20000)</td>
<td>{F}</td>
</tr>
</tbody>
</table>

We shall compute $\|\text{Possibly } \Phi\|$ where $\Phi$ is given by (26). First we transform $\Phi$ into SDNF, which yields formula (27). This formula is a disjunctcon of 6 elementary formulas, $\Phi_1 \lor \ldots \lor \Phi_6$, where $\Phi_i$ is of the form $(t_{i0} = 0) \land \bigwedge_{k=1}^{n} (t_{ik} \neq 0)$ ($t_{i0}$ may be 0). By using (29), (30) and Theorem 4.3 we obtain

$\|\text{Possibly } \Phi_1\| = T$, since $\|\text{surely } t_{10}\| = \{x_1\} = \emptyset$,

$\|\text{Possibly } \Phi_2\| = F$, since no SDR exists for $t_{10}$,

$\|\text{Possibly } t_{21}\| = \{x_4\}$, $\|\text{Possibly } t_{22}\| = \{x_4\}$, $\|\text{Possibly } t_{23}\| = \{x_1,x_2\}$,

$\|\text{Possibly } \Phi_3\| = F$, since no SDR exists for $t_{31}$,

$\|\text{Possibly } t_{31}\| = \{x_1\}$, $\|\text{Possibly } t_{32}\| = \{x_4\}$, $\|\text{Possibly } t_{33}\| = \{x_1\}$,

$\|\text{Possibly } \Phi_4\| = F$, since no SDR exists for $t_{41}$,

$\|\text{Possibly } t_{41}\| = \{x_1\}$, $\|\text{Possibly } t_{42}\| = \{x_4\}$, $\|\text{Possibly } t_{43}\| = \{x_1,x_2\}$.

Consequently, $\|\text{Possibly } \Phi\| = T$ (we need not consider $\Phi_5$ and $\Phi_6$).

It is easy to see that the length of the SDNF may, in general, grow exponentially when the length of a formula gets large. Notice, however, that any straightforward method of evaluating $\|\text{Possibly } \Phi\|$ based on enumerating all completions of $\mathcal{S}$ would
be incomparably worse, since the number of such completions is, in general, an exponential function of the number of objects. (Strictly speaking, the number of completions may be infinite when an attribute domain is infinite. However, we do not need the exact value of an attribute \( j \) in a completion — it is sufficient to know the subset \( C \in C_j(\Phi) \) to which it belongs.) For obvious reasons, our simple example could not illustrate the fact that in a real data base the number of objects is usually several orders of magnitude bigger than the length of a query.

Some ways of improving the efficiency of our method of evaluating \( \|Possibly \Phi\| \) are listed below:

1. In order to transform (25) into SDNF we may repeatedly apply the equivalence

\[
(v_k = 0) \land (v_l = 0) \approx (v_k \land v_l = 0) \lor ((v_k = 0) \land (v_l \lor = 0))
\]

and the Distributive Law to formulas \((v_k = 0), (v_l = 0)\) such that \(v_k \land v_l \in \not\varepsilon.\) The resulting SDNF contains, in general, fewer elementary formulas.

In particular, we skip Steps 5 and 6 whenever (25) is already an elementary formula.

2. We need not transform (24) into SDNF if we find that \(\|surely t_0\| = \bot\) (the value of \(\|Possibly \Psi\|\), where \(\Psi\) given by (24), is then \(F\)). After having generated an elementary formula \(\Phi_i\) we may evaluate \(\|Possibly \Phi_i\|\), and if it is \(T\), we need not continue the transformation process (the value of the whole formula 

3. Testing for the existence of an SDR can be simplified by using the following simple combinatorial facts:

\[(a) \quad \text{If } S_k = \emptyset \text{ for some } k, \text{ then no SDR exists for } S_1, \ldots, S_n\]
(b) If \( x \in S_k \setminus (S_1 \cup \ldots \cup S_{k-1} \cup S_{k+1} \cup \ldots \cup S_n) \) then
\[
S_1, \ldots, S_n \text{ has an SDR} \iff S_1, \ldots, S_{k-1}, S_{k+1}, \ldots, S_n \text{ has an SDR.}
\]

(c) If \( |S_k| \geq n \) then
\[
S_1, \ldots, S_n \text{ has an SDR} \iff S_1, \ldots, S_{k-1}, S_{k+1}, \ldots, S_n \text{ has an SDR.}
\]

(a) corresponds to \( \|\text{possibly } t_k\|_{\mathcal{F}} = \emptyset \), and (b) to \( \|\text{surely } t_k\|_{\mathcal{F}} = \emptyset \), since \( t_k \cdot t_i \approx 0 \) implies
\[
\|\text{possibly } t_k\|_{\mathcal{F}} \setminus \|\text{possibly } t_i\|_{\mathcal{F}} \geq \|\text{surely } t_k\|_{\mathcal{F}} \setminus \|\text{surely } t_i\|_{\mathcal{F}}
\]
\[
= \|\text{surely } t_k\|_{\mathcal{F}} \cap \|\text{surely } \neg t_i\|_{\mathcal{F}} = \|\text{surely } t_k \cdot \neg t_i\| = \|\text{surely } t_k\|_{\mathcal{F}} = \emptyset.
\]

4. If \( t_0 \) is 0 in an elementary formula \( \Psi \), and \( \|\text{Possibly } \Psi\| = T \) for a subset of our collection of objects, then \( \|\text{Possibly } \Psi\| = T \) for the whole collection. It is not necessary so when \( t_0 \) is not 0 — then the existence of an SDR for \( \|\text{possibly } t_1\|, \ldots, \|\text{possibly } t_n\| \) is preserved under adding new objects, but the condition \( \|\text{surely } t_0\| = \emptyset \) may be violated.

By the last remark, we may infer that the value of \( \text{Possibly } \Phi \), where \( \Phi \) given by (26), is \( T \) in any system which — when represented by a table — contains the four rows from Example 6.3.

**Example 6.4.** Let \( \Phi \) be the formula
\[
(((\text{HAIR} = \text{FAIR}) \cdot \text{possibly } (\text{SEX} = F)) = 0)
\]
\[
\land \text{Surely } ((\text{SAL} > 50000) \cdot (\text{TAX} < 5000) = 0)
\]
The first part of this formula can be transformed into
\[
(\text{HAIR} = \text{FAIR}) \rightarrow (\text{SEX} = M) = 0
\]
(the left hand side is in both WANF and WMNF, which enables us to easily compute
its value in any system). In order to evaluate the second part of our formula we might exploit the general method based on transforming into SDNF. It is, however, not necessary in our simple example (neither is it necessary in most of the queries likely to arise in practice). Instead, we may use the first of the following four equivalencies:

\[
\text{Surely (} t = 0 \text{)} \Leftrightarrow_i (\text{possibly } t = 0)
\]

\[
\text{Surely (} t \neq 0 \text{)} \Leftrightarrow_i (\text{surely } t \neq 0)
\]

\[
\text{Possibly (} t = 0 \text{)} \Leftrightarrow_i (\text{surely } t = 0)
\]

\[
\text{Possibly (} t \neq 0 \text{)} \Leftrightarrow_i (\text{possibly } t \neq 0)
\]

(t is an arbitrary special term; the easy proof of these equivalencies is left to the reader). We have

\[
\text{possibly (} \langle \text{SAL} > 50000 \rangle \cdot \langle \text{TAX} < 5000 \rangle \rangle
\]

\[
\Leftrightarrow_i \langle \text{SAL} \leq 50000 \rangle \cdot \langle \text{TAX} \geq 5000 \rangle
\]

(see axiom (viii)*), and consequently our formula is transformed into the form

\[
\langle \langle \text{HAIR} = \text{FAIR} \rangle \cdot \langle \text{SEX} = \text{M} \rangle = 0 \rangle
\]

\[
\wedge \langle \langle \text{SAL} \leq 50000 \rangle \cdot \langle \text{TAX} \geq 5000 \rangle = 0 \rangle
\]

which easily lends itself to evaluation in any system.

In the above example we have eliminated Surely from our formula. This is, however, not always possible. The reason for this impossibility is, very roughly speaking, the fact that the existence of an SDR is not a "Boolean" property — there may be two sequences, \( S_1, \ldots, S_n \) of subsets of \( X \), and \( T_1, \ldots, T_n \) of subsets of \( Y \) such that

\[
S_1^{\epsilon_1} \cap \ldots \cap S_n^{\epsilon_n} = \emptyset \iff T_1^{\epsilon_1} \cap \ldots \cap T_n^{\epsilon_n} = \emptyset
\]

for all \( \epsilon_1, \ldots, \epsilon_n \in \{0,1\} \), yet \( S_1, \ldots, S_n \) has an SDR, while \( T_1, \ldots, T_n \) does not have any
SDR. This is so, for instance, in the case of the sequences \(x,y\), \(x,y\) and \(x\), \(x\). It is easy to see that formulas not containing *Surely* express "Boolean" properties of the values of special terms. On the other hand, we know (see Theorem 6.2) that there are special formulas of the form *Possibly* \(\Psi\) which express the existence of an SDR — a "non-Boolean" property — for the values of some special terms. Of course, no such formula can be replaced by any (internally) equivalent formula not containing *Surely*.

For example, let us consider a system with \(\beta_{\text{sex}}(x) = \{F,M\} = D_{\text{sex}}\) for all \(x \in X\), and let \(\Phi\) be the formula *Possibly* \(((\text{sex} = F) \neq 0) \land (\text{sex} = M) \neq 0\)). Of course, if \(|X| = 1\) then \(\|\Phi\| = F\), and if \(|X| = 2\) then \(\|\Phi\| = T\). However, the value of any formula not containing *Surely* is the same in both cases. Indeed, the value of any special term is either \(\varnothing\) in both cases or \(X\) in both cases, and hence the value of any atomic formula is the same in both cases.

To conclude this section, let us mention that the values \(\|\text{surely } t\|\), \(\|\text{possibly } t\|\), \(\|\text{Surely } \Phi\|\), and \(\|\text{Possibly } \Phi\|\) (for simple \(t\) and \(\Phi\)) were denoted in [11] by \(\|t\|_{\varnothing}\), \(\|\|\|\), \(\|\Phi\|_{\varnothing}\), and \(\|\Phi\|\), respectively (\(\|\|\|\) and \(\|\|\) were called the lower value and the upper value, respectively). Our algorithm of computing \(\|\text{Possibly } \Phi\|\) gives a method to determine \(\|\Phi\|\) (and \(\|\Phi\|_{\varnothing}\), since \(\|\Phi\|_{\varnothing} = \neg\|\neg\Phi\|\)), a problem which was left open in [11].
7. OTHER INTERPRETATIONS OF QUERIES

There us another approach to semantics of queries in an incomplete information system, based on the theory of pseudo-Boolean algebras (PBAs) and intuitionistic logic. (The relation of PBAs to intuitionistic logic is exactly the same as the relation of TBAs to modal logic S4, see [3,15].) We shall describe only the pseudo-Boolean approach to interpreting terms (intuitionistic interpretation of formulas is considered in [13]). In the pseudo-Boolean approach we consider only simple queries, and we treat "¬" as a "strong" negation, i.e., ¬t is understood, roughly speaking, as the set of objects known not to have property t, instead of just not known to have property t. Also the interpretation of "→" is "strong". The formal definition of the "pseudo-Boolean value" of a simple term t — denote it by |t|_φ — can be obtained by changing (iii) and (vi) in Definition 3.1 to

\[ |\neg t|_\phi = \{ x \in X: \text{ for every } \mathcal{S}' \supseteq \mathcal{S}, x \notin |t|_\phi \} \]

\[ |t \rightarrow s|_\phi = \{ x \in X: \text{ for every } \mathcal{S}' \supseteq \mathcal{S}, x \notin |t|_\phi, \text{ or } x \notin |s|_\phi \} \]

(and deleting (vii)). It can easily be shown that for any simple term t

\[ |t|_\phi = \|\tau(t)\|_\phi \]

where \( \tau(t) \) is defined inductively by

(i) \( \tau(0) = 0, \quad \tau(1) = 1 \)

(ii) \( \tau(t + s) = \tau(t) + \tau(s) \)

(iii) \( \tau(t \cdot s) = \tau(t) \cdot \tau(s) \)
(iv) \( \tau(-t) = \Box - \tau(t) \)

(v) \( \tau(t + s) = \Box (\tau(t) \rightarrow \tau(s)) \)

It is also not difficult to prove that

\[
\|\text{surely } t\|_\mathcal{F} = \overline{-t}_\mathcal{F}
\]

\[
\|\text{possibly } t\|_\mathcal{F} = X \setminus \overline{-t}_\mathcal{F}
\]

Similar relations between \(\|\cdot\|\) and \(\cdot\) exist for formulas. These relations reflect the fact that the set of open elements of any TBA \(a \text{ is open if } a = \mathbb{I}a\) forms a PBA, and they are connected with the well known interpretation of intuitionistic logic within the modal logic S4 (see [15,3]). It may be noted that there exists a similarity between a "pseudo-Boolean value" and the Kripke models for the intuitionistic logic (Kripke [9], see also Fitting [3]). It can also be shown that \(\cdot\) \(\|\cdot\|_\mathcal{F}\) coincides with the interpretation of terms defined — in a quite different way — by Jaegermann [7].

In the internal interpretation of queries presented in this paper we consider, for any incomplete system \(\mathcal{S}\), the set of all extensions of \(\mathcal{S}\). Since \(\mathcal{S}\) represents an incomplete knowledge about a reality described by a completion \(\mathcal{S}^*\) of \(\mathcal{S}\), not all of these extensions are really possible. The only completions accessible in reality are those consistent with \(\mathcal{S}^*\), i.e. those of which \(\mathcal{S}^*\) is a completion. Hence, we may consider a different approach, where the partially ordered set of all extensions of \(\mathcal{S}\) is replaced by

\[
[\mathcal{S}, \mathcal{S}^*] = \{\mathcal{S}' : \mathcal{S} \leq \mathcal{S}' \leq \mathcal{S}^*\}
\]
Of course, in general we do not know $S^*$. However, there are formulas, such as

$$\Box \Diamond f = \Diamond \Box f, \quad \Box \Diamond \phi \equiv \Diamond \Box \phi$$

which are true for any $S$ and for any completion $S^*$ of $S$. (The interpretation of a term and of a formula is now the same as in Definition 3.1, but with "for every $S' \supseteq S^*$..." replaced by "for every $S'' \in [S, S^*]..."." These universally valid formulas define a logic, quite different from the one inherent in our internal interpretation described in Section 4. Notice that this logic describes the process of increasing the user's (system's) knowledge, as seen by an observer who has complete information about both the system ($S$) and reality ($S^*$).
8. CONCLUSIONS

Following a treatment of more elementary topics in [11], in the present paper we gave a thorough treatment of the internal interpretation of queries. It turned out that this interpretation leads in a natural way to the notion of a topological Boolean algebra and to a modal logic related to S4. These notions were shown to play the same role for the internal interpretation as Boolean algebras and classical logic in the case of external interpretation. We presented a complete axiom system for internally equivalent transformations of terms, and a method to compute the internal interpretation for arbitrary terms, and for a broad class of formulas including most formulas of practical interest.

The number of steps performed by our algorithms may, in the worst case, be an exponential function of the length of the query. However, they seem to be of practical interest for real world queries that are likely to be submitted to a data base.

There is a number of interesting problems which remain open. One such problem is to investigate in more detail the logic involved in the internal interpretation of formulas. More specifically, it is not known to the author whether this logic is decidable (it may be noted that the results of Section 4 can easily be used to develop a decision procedure for atomic formulas). Another question is whether there is a simple axiom system for this logic. Both problems are open even for the sublanguage considered in Section 5.
ACKNOWLEDGMENTS. I am indebted to many individuals for their assistance at various stages of the development of this paper. My special thanks are due to W. Marek and Z. Pawlak who encouraged me to work on the problem of incomplete information. I have benefitted greatly from discussions with M. Jaegermann, J. Łoś, C. Rauszer and K. Segerberg. The suggestions of anonymous referees resulted in a considerable improvements in the presentation of the results of the paper.
